7	Summary.	21

Edge plasma temperature has nothing to do with the wall temperature

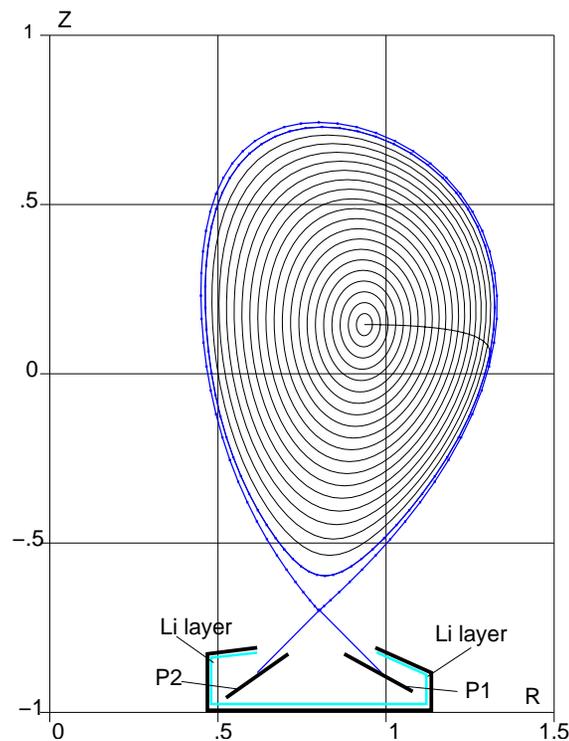

Mean free path of the deuterium ion

$$\begin{aligned}
 \tau &= 3 \cdot 10^6 \frac{T_e^{3/2}}{Z^3 n_i (\lambda_C / 10)} \sqrt{\frac{\mu}{2}}, \\
 \lambda_C &= 23 - \ln \sqrt{\frac{2n_{20} \cdot 10^5}{T_{i,keV}^3}} = 16.9 - \frac{1}{2} \ln \frac{n_{20}}{T_{i,keV}^3}, \\
 \tau_{DD} &= 2 \cdot 10^{-2} \frac{T_{keV}^{3/2}}{n_{20}}, \\
 V_D \left[\frac{m}{sec} \right] &= 219 \cdot 10^3 \sqrt{T_{keV}}, \\
 \lambda_D &= V_D \tau_{DD} = 4380 \frac{T_{keV}^2}{n_{20}}.
 \end{aligned} \tag{1.1}$$

Plasma, impacting the PFC, has no idea about the temperature of the wall.

**Any fusion relevant plasma is in a collisionless regime
near the wall**

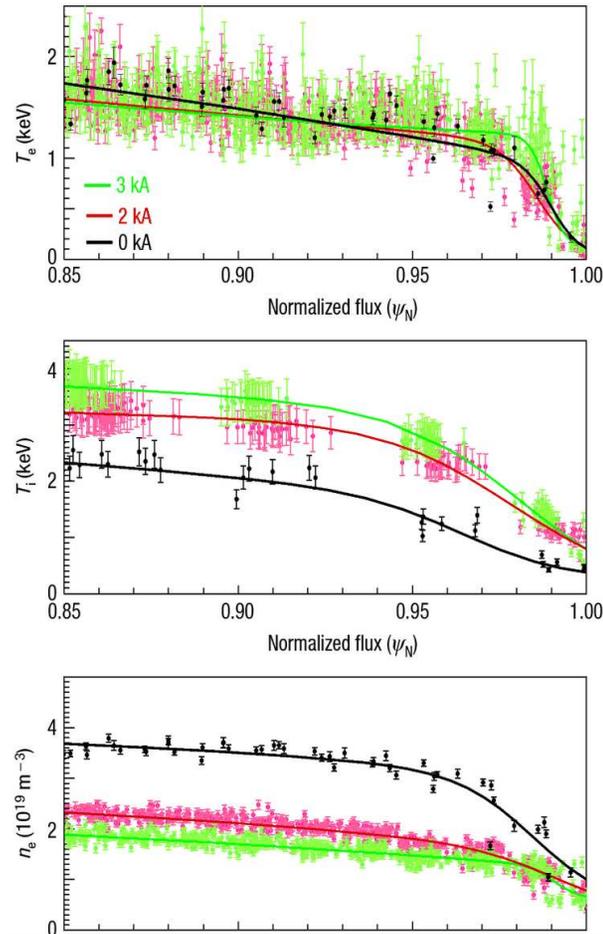

(Pumping lithium plasma facing surface + core fueling) together provide a high edge temperature pedestal, the best possible, diffusion based, confinement, global stability and controlled plasma-wall interaction

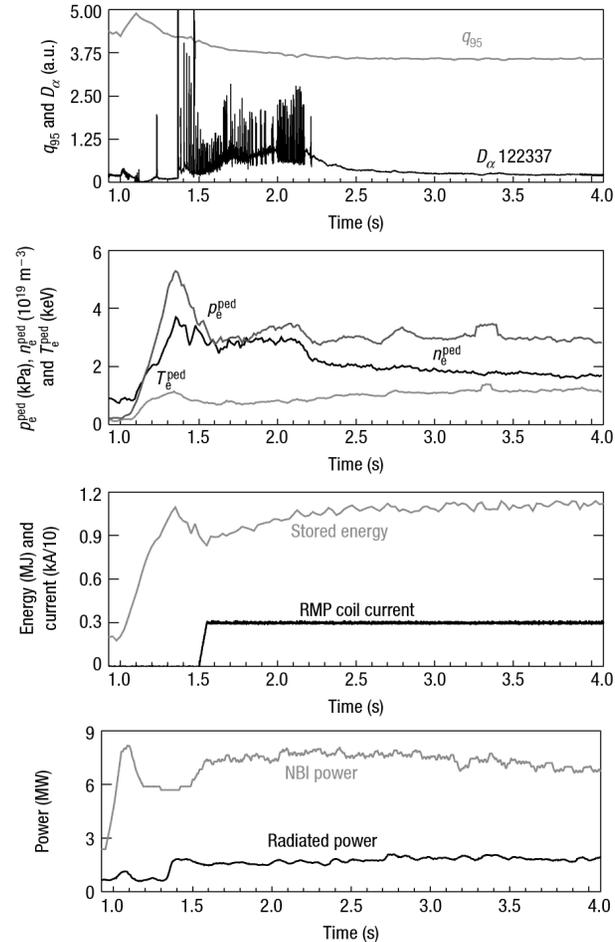

1. In collisionless SOL the thermo-force $R_T \propto Z^2$, driving impurities into the plasma. is absent, leading to $Z_{eff} \simeq 1$
2. Blobs and direct plasma-wall interaction are also not expected. There is no indications of blobs in QHM regime on D-IIID.

LiWall plasma regime, not the plasma with the C- or W-walls, is the only science based concept of the stationary plasma

RMP experiments on D-IIID have confirmed our, LiWF, views

0 kA, 2 kA, 3 kA $I_{RMP-coil}$

T.Evans at al., Nature physics 2, p.419, (2006)

Plasma T_{edge} has nothing to do with the “edge transport barrier”

2 What is the High performance (LiWall) regime for NSTX?

Reference Transport Model (RTM) is expected for the LiWall regime

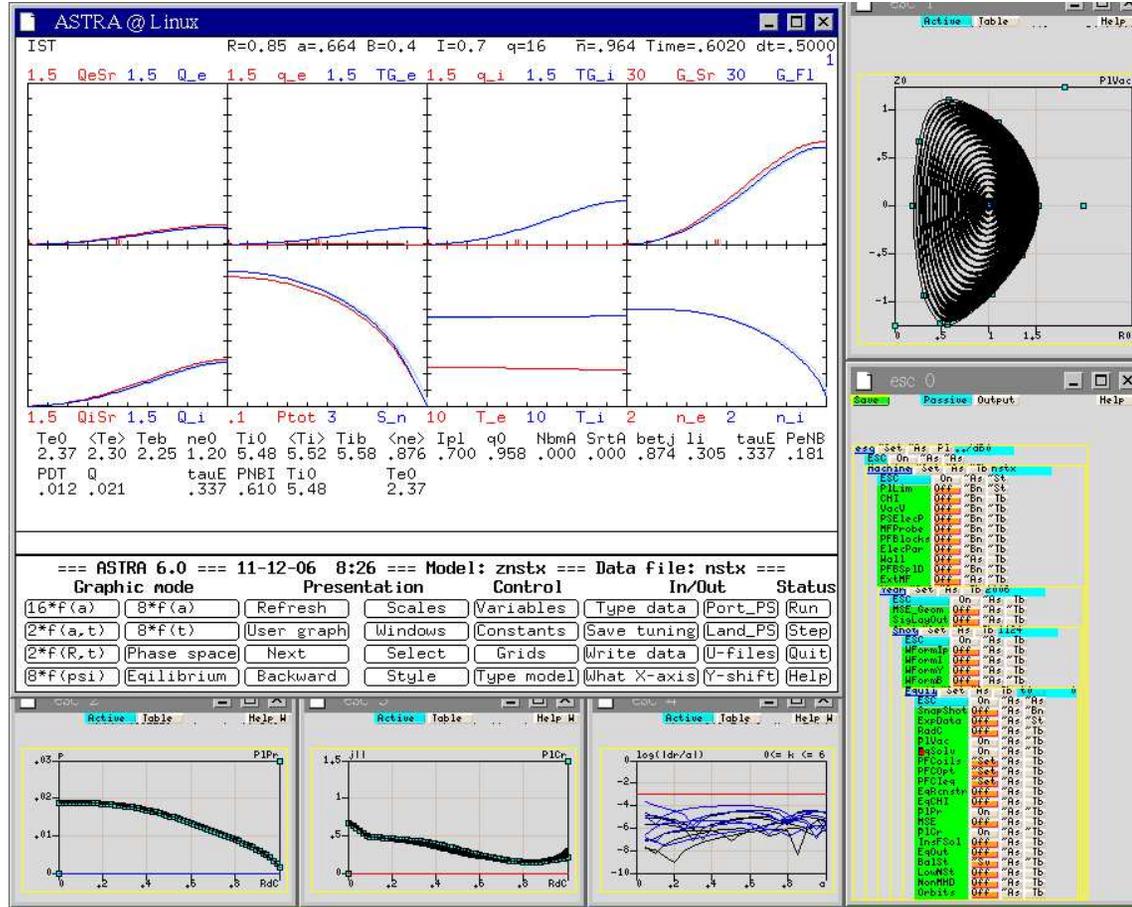

$$\begin{aligned}
 q_i &= \chi_i^{neo-classics} \nabla T_i, & \text{not important,} \\
 q_e &= \chi_i^{neo-classics} \nabla T_e, & \text{not important,} \\
 \Gamma_{i,e} &= \chi_i^{neo-classics} \nabla n
 \end{aligned}
 \tag{2.1}$$

The Table compares the RTM predictions (ASTRA-ESC) with CDX-U data.

Parameter	CDX-U	RTM	RTM-0.8	RTM-0.7	RTM-0.65	glf23
$\dot{N}, 10^{21} \text{part/sec}$	1-2	1	0.5	0.35	0.3	0.8-3
β_j	0.150	0.151	0.150	0.150	0.151	0.145
l_i	0.66	0.769	0.702	0.694	0.671	0.877
V, Volt	0.5-0.6	0.77	0.53	0.48	0.40	0.85
τ_E , msec	3.5-4.5	2.7	3.8	4.8	5.3	2.3
$n_e(0), 10^{19} \text{part}/m^3$		0.9	0.7	0.596	0.590	0.9
$T_e(0)$, keV		0.308	0.366	0.391	0.413	0.329
$T_i(0)$, keV		0.031	0.029	0.028	0.030	0.028

RTM does not contradict CDX-U measurements and equilibrium reconstruction

ASTRA-ESC simulations of NSTX, B=0.4 T, I=0.7 MA, 0.6 MW, 20 keV NBI

Hot-ion mode:

$$T_i = 5.5 \text{ [keV]},$$

$$T_e = 2.5 \text{ [keV]},$$

$$n_e(0) = 0.14 \cdot 10^{20},$$

$$\tau_E = 0.33 \text{ [sec]},$$

$$P_{NBI} = 0.61 \text{ [MW]}$$

NBI energy should be consistent with the plasma temperature:

$$E_{NBI} = 2.5(T_i + T_e)$$

LiWall regime is an extension of QHM or low-collisionality H-mode beyond their plasma density limitations

3 What is the Pumping Lithium Divertor (PLD) ?

PLD \equiv actively cooled plates with flowing $h \simeq 0.1$ mm Li layer

Gravity, Marangoni effect, residual $\mathbf{j} \times \mathbf{B}$ forces,

$$V_g = \frac{\rho g h^2}{2\nu} \sin \theta = 0.049 \sin \theta \text{ [m/s]}, \quad (3.1)$$

$$V_M = \frac{d\sigma(T)}{dT} \frac{h \nabla T}{\nu} = 0.8 h \nabla T \text{ [m/s]}$$

are sufficient for replenishing Li surface.

Lithium can accept 5-10 MW/m² and keep $T_{Li} < 400^\circ\text{C}$

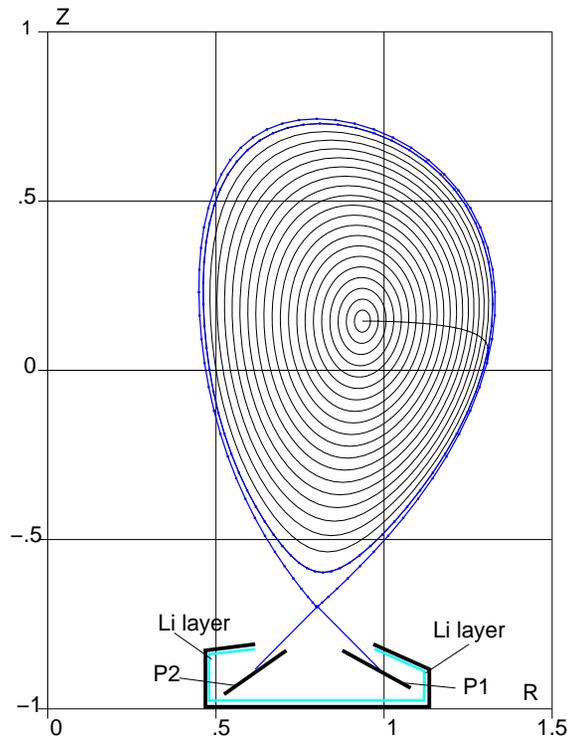

$$\chi_{Li} = 47.6,$$

$$\Delta T \text{ [}^\circ\text{C]} = 100 \frac{q}{4.7} \cdot h \left[\frac{\text{MW}}{\text{m}^2} \cdot \text{mm} \right]. \quad (3.2)$$

For any PFC (W,C,Li) power extraction are limited

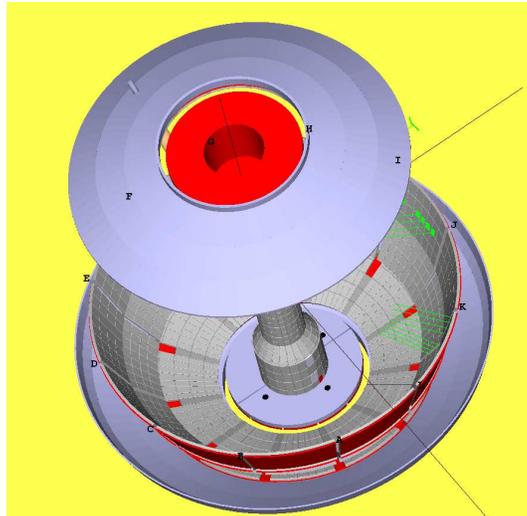

by the coolant temperature,

rather than by PFC surface temperature.

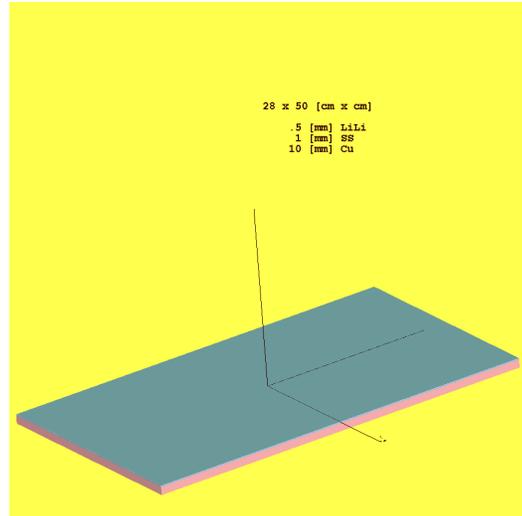

There is no contradiction between T limitations for Pumping Li Divertor and high efficiency of power production

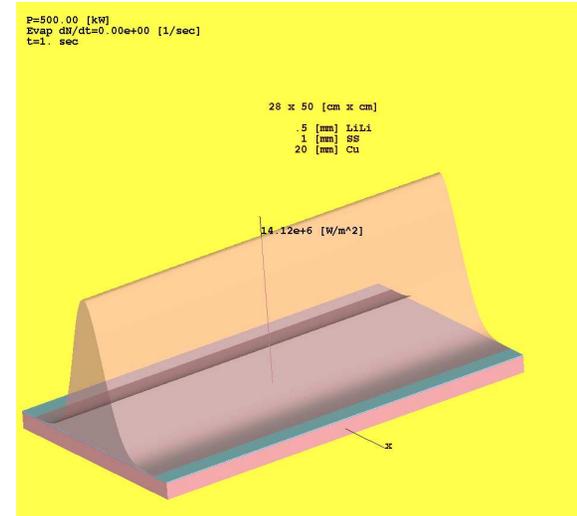

Lithium Loaded Target Plate (LLTP) can provide 10000 active monolayers or $\simeq 3\mu\text{m}$ of molten Li necessary for NSTX.

Li coated plate in low inner divertor

Li/SS/Cu (0.5mm/1mm/10mm) sandwich with a trenched surface

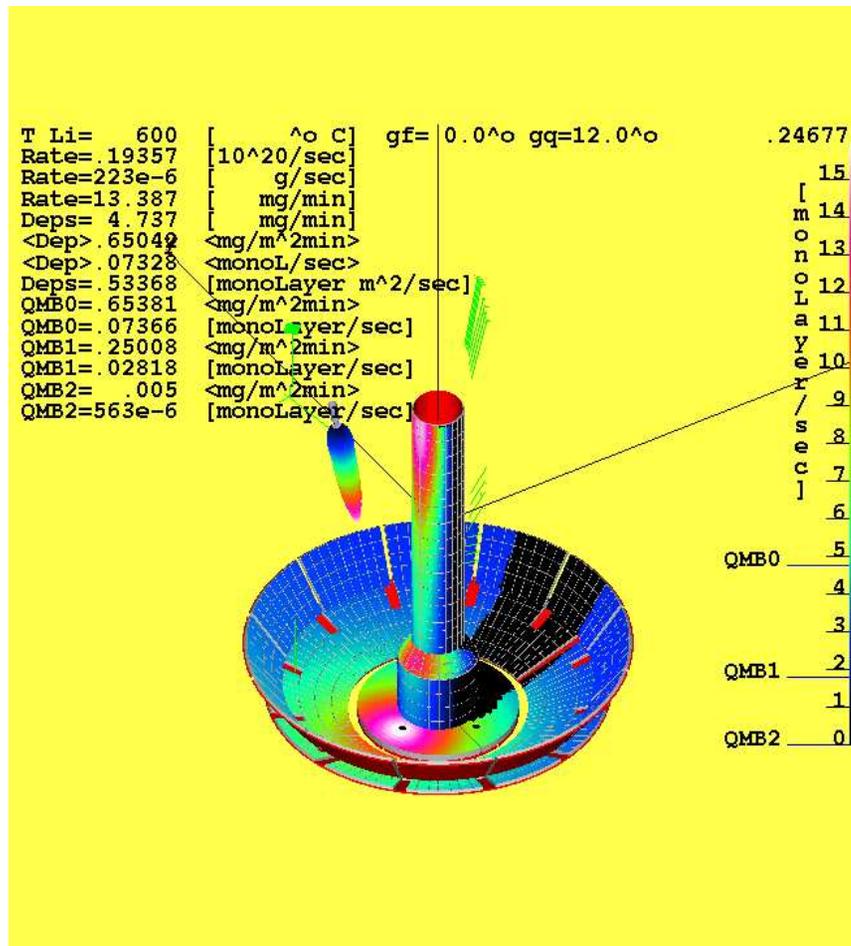

Gaussian (8 cm wide) heat deposition profile

$$\begin{aligned}
 S &\simeq 0.75 [m^2], \quad L_{SOL,m} = 2.5, \quad V_{Li} \simeq 0.35 [L], \quad M_{Li} \simeq 175 [g], \\
 \nu_{Pa \cdot sec} &= 4.2 \cdot 10^{-4}, \quad I_{ion,MA} = \frac{(0.4 - 1) \cdot 10^{-3}}{1.6}, \\
 V_{Li,cm/sec} &= (2 - 5) \cdot B_{tor} \frac{h_{Li,mm}^2}{0.01} \frac{0.1}{w_{SOL}} \frac{I_{SoL,MA}}{I_{ion}}
 \end{aligned} \tag{3.3}$$

Li/SS/Cu plate could be real first step toward PLD and LiW regime

Solid lithium provides only 150 active monolayers

There is no a meaningful concept of Li on C- based PFC.

Evaporator at the top of NSTX is extremely inefficient in delivering lithium to the low divertor

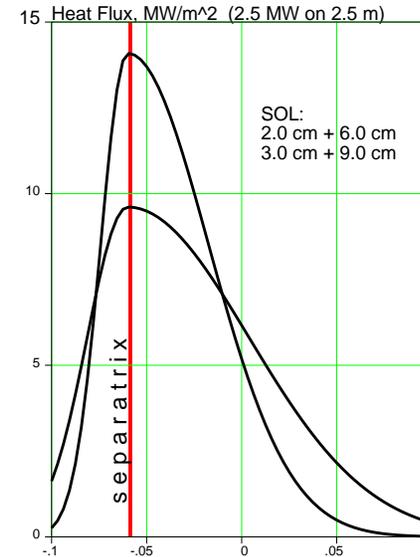

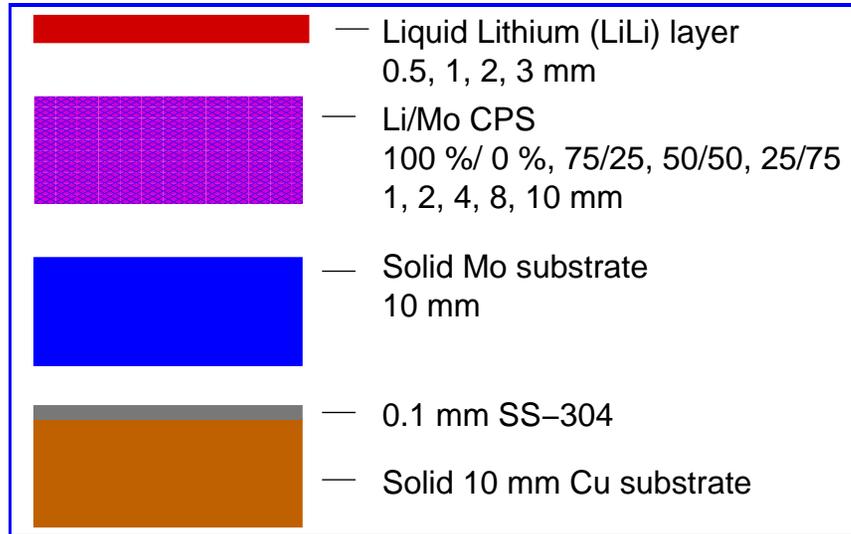

R_n [cm]	θ_{aim}	<IDL-2>	<IDL-1>	<OD-L>
1.03	22.0°	2.657%	1.512%	12.824%
1.03	12.0°	3.449%	2.252%	14.170%
1.53	22.0°	2.675%	1.535%	12.978%
1.53	12.0°	3.168%	1.962%	14.307%

NSTX evaporator cannot meet the requirements of plasma pumping.

In contrast, Li pellets together with the LLTP may work

4 Thermal model for the Li loaded target plate

Both Liquid Lithium (LiLi) and Li/Mo CPS were considered

Heat flux profile from the SOL

$$Q_{SOL} = Q_0 \exp \left[- \left(\frac{x - x_0}{d(x)} \right)^2 \right], \quad \begin{cases} d = d_{out}, & x \geq x_0 \\ d = d_{in}, & x < x_0 \end{cases} \quad (4.1)$$

Characteristic scale lengths, mm

d_{in}	d_{out}	Δ_{LiLi}	$\Delta_{Li/Mo}$	Δ_{SS}	$\Delta_{Mo,Co}$	Li/Mo CPS
20,30	$3d_{in}$	0.5, 1,2,3	1,2,4,8,10	.1	10	4/0, 3/1, 2/2, 1/3, 0/4

Initial temperature is very important for limits by evaporation

The expected working range of $P_{NBI} \simeq 0.75-1.5$ MW. The range of P_{NBI} considered: 0-2.5 MW deposited to LLD.

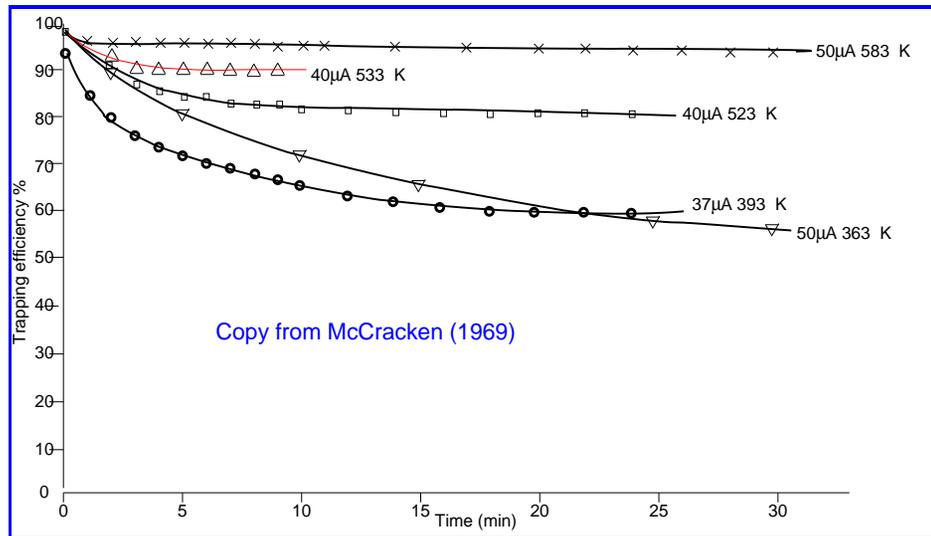

Initial temperatures:

- 100°C, solid lithium, although *heat losses for melting of Li have been neglected (!) (additional reserve of $\Delta T \simeq 100^\circ\text{C}$ for the Li/SS/Cu plate).*
- 200°C, liquid lithium.

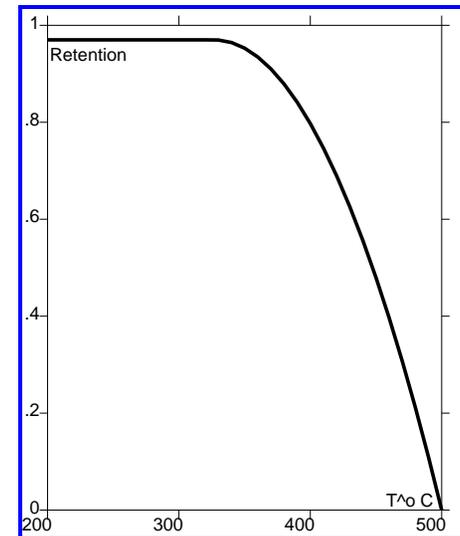

Surface area 0.7 m² contains 10^{19} Li particles/monolayer, or $3 \cdot 10^{26}$ Li particles/mm of thickness.

**1 working mm of Li is sufficient for pumping 10^4 of $3 \cdot 10^{21}$ D,
more than sufficient for 2 weeks of NSTX operation**

Lithium retains Hydrogen in a limited window of temperatures

McCracken retention curves

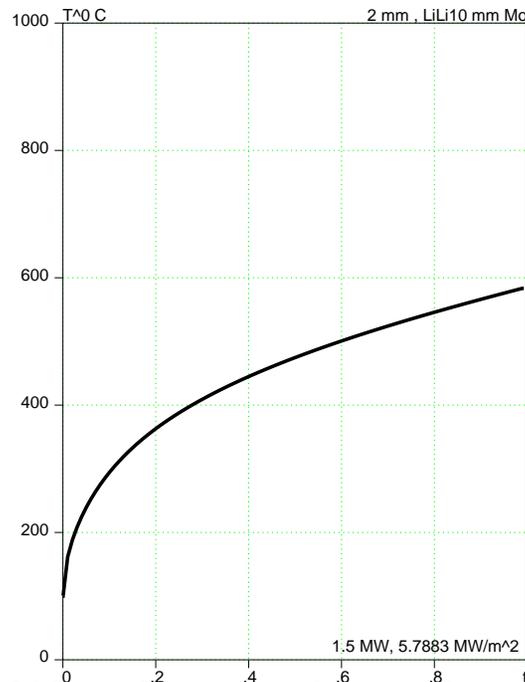

Short term retention curve used in calculations

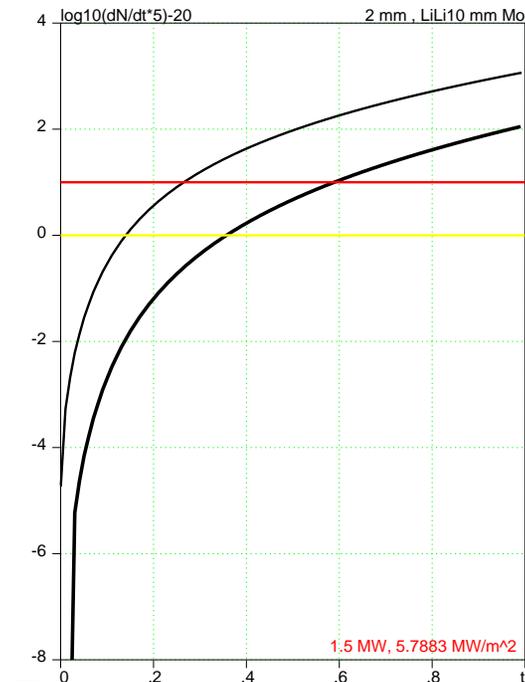

Probably short lasting retention allows temperatures above 350°C (R.Majeski)

Short term retention curve was taken arbitrarily
Requires special technology studies

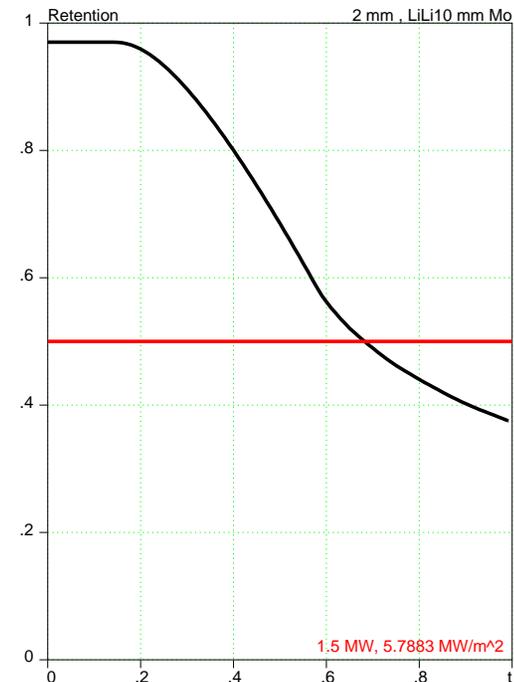

3-D Cbebm code (written for Marangoni effect) is used to simulate heating of Li surface

Waveform of surface temperature T_{Li}

Evaporation $\log_{10}(dN/dt) - 20$

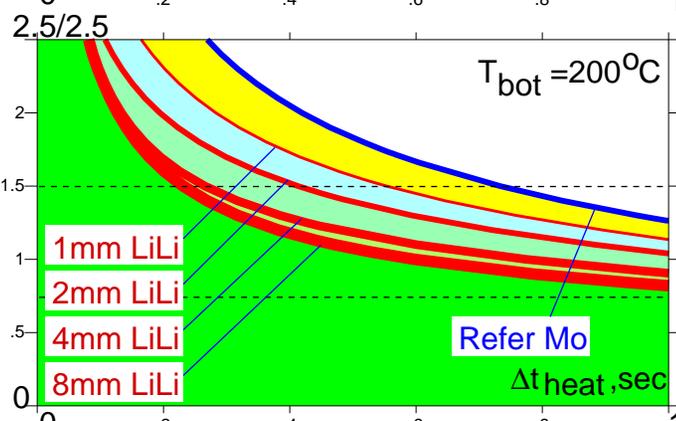

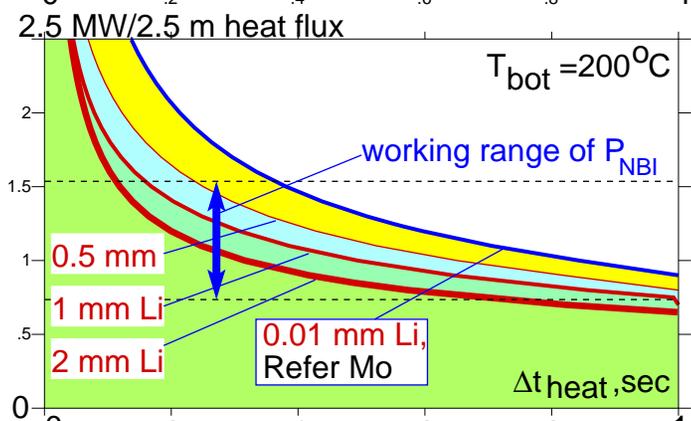

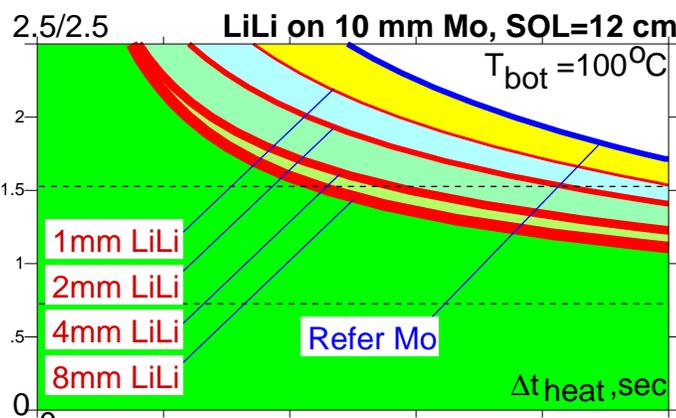

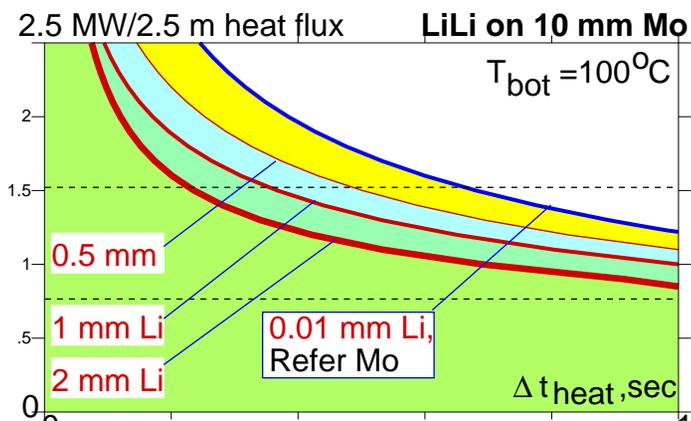

Overall retention

Evaporation limit was set to 10^{21} 1/sec

The role of reduction in retention after 350° is unknown

5 Operational space for Mo sponge based LLD

Operational space is limited by evaporation limit

$$d_i = 2, d_e = 6 \text{ cm}$$

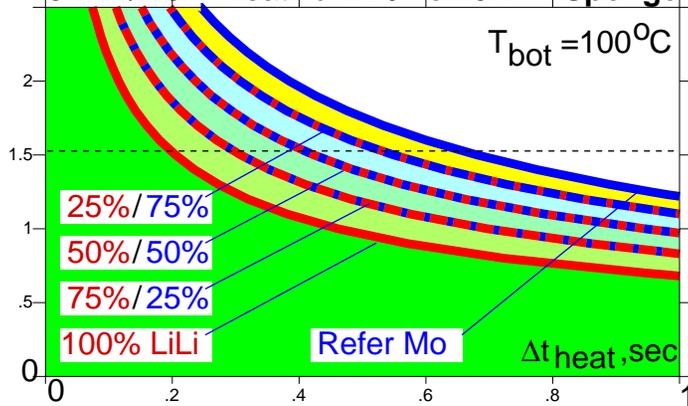

$$d_i = 3, d_e = 9 \text{ cm}$$

Operational space is situated between the axis and the curve for each case.

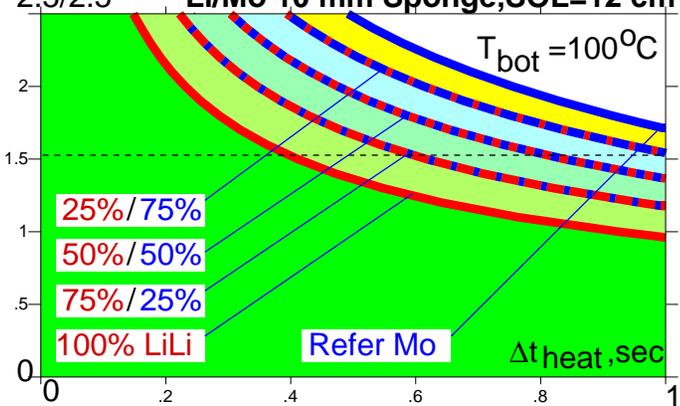

100° of initial ΔT is equivalent to 3 cm of d_{SOL}

Regarding the thermal regime, CPS has advantage over LiLi

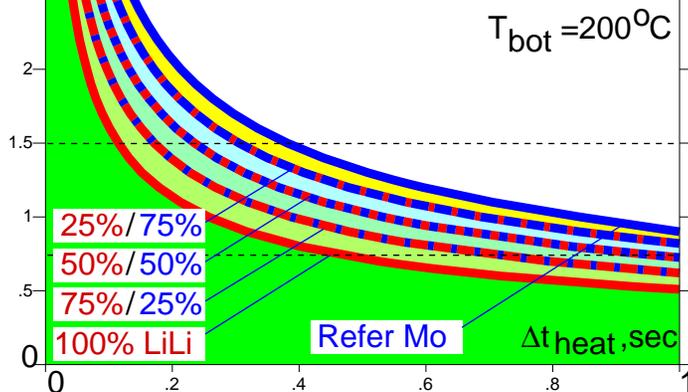

2.5 MW/2.5 m heat flux Li/Mo 10 mm Sponge

2.5/2.5 Li/Mo 10 mm Sponge, SOL=12 cm

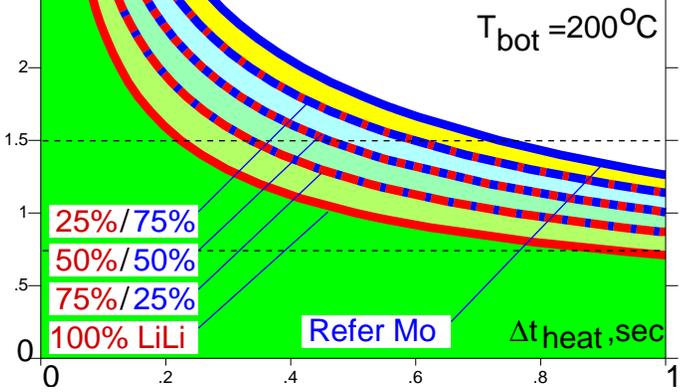

2.5 MW/2.5 m heat flux

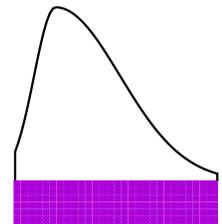

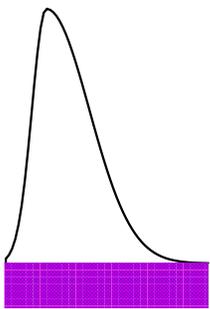

$d_i = 2, d_e = 6 \text{ cm}$

2.5 MW/2.5 m heat flux

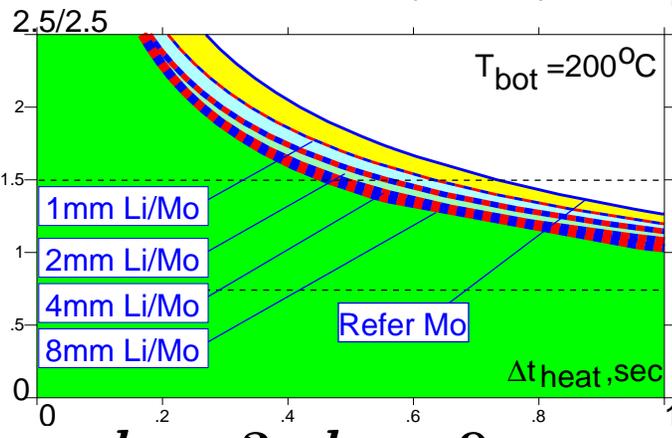

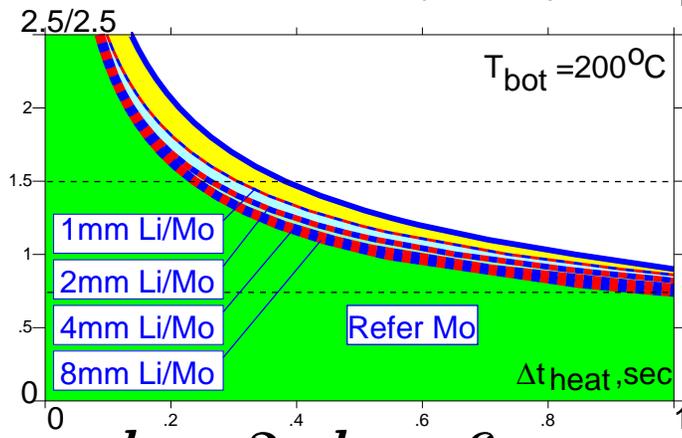

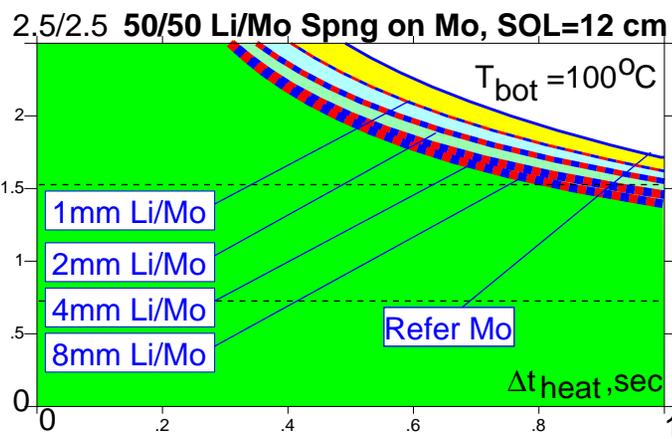

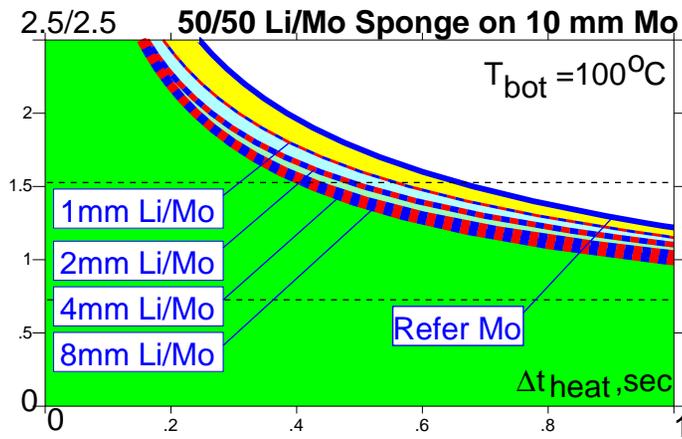

$d_i = 3, d_e = 9 \text{ cm}$

$\chi_{Li/Mo} = C_{Li}\chi_{Li} + (1 - C_{Li})\chi_{Mo}$ requires technology test

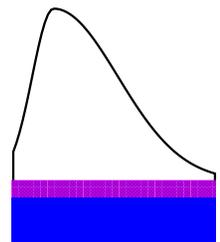

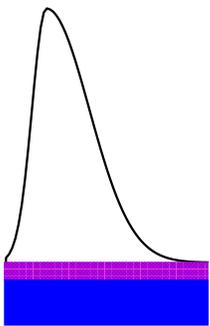

50/50 Li/Mo CPS may have the best characteristics

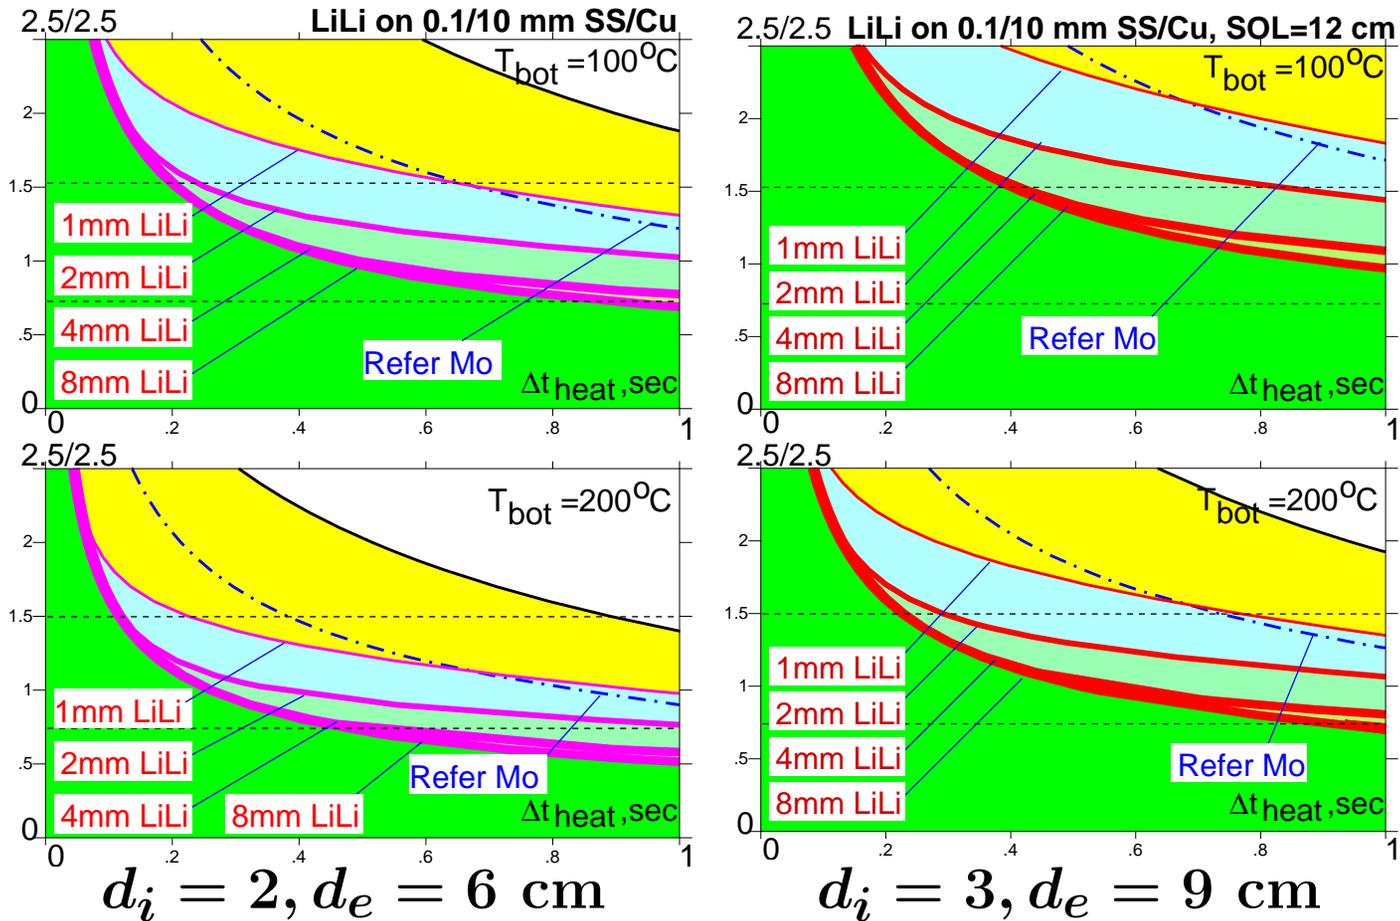

$d_i = 2, d_e = 6$ cm

$d_i = 3, d_e = 9$ cm

Potential clogging by LiOH, LiD, etc requires technology studies

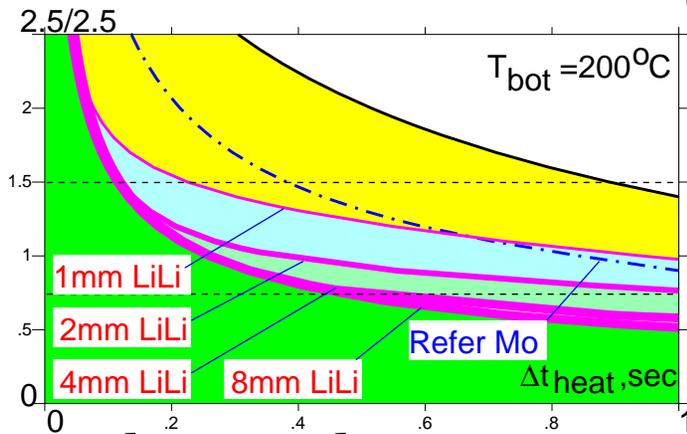

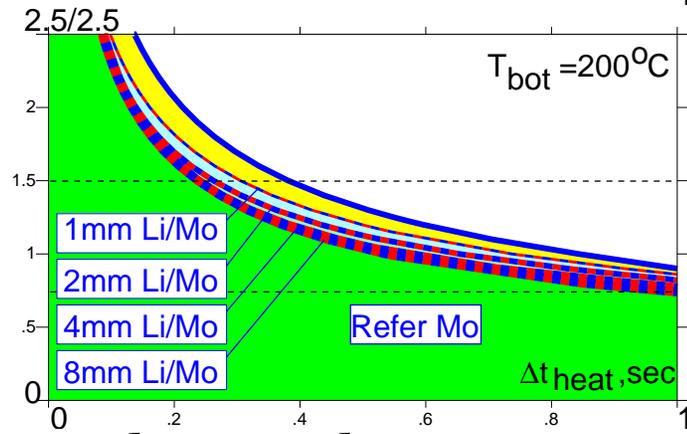

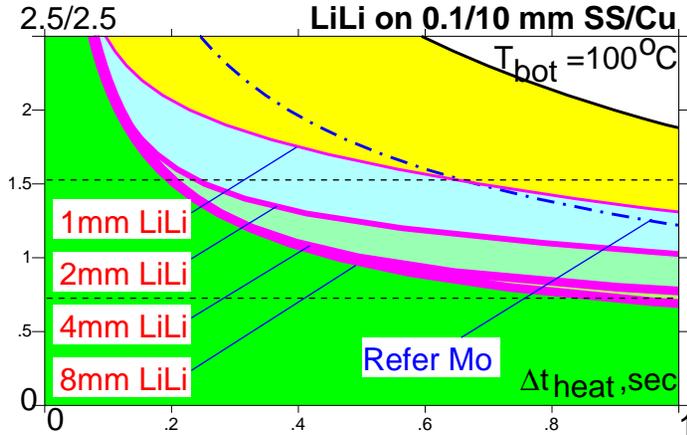

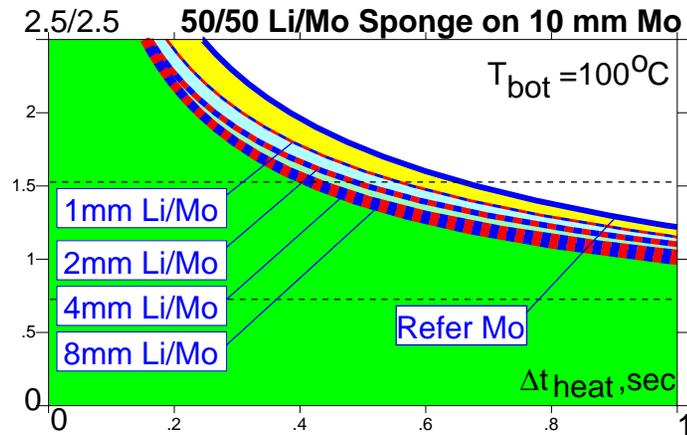

The plate 0.1-1 mm of Li on 0.1/10 SS/Cu provides the operational space for LiWall regime in NSTX

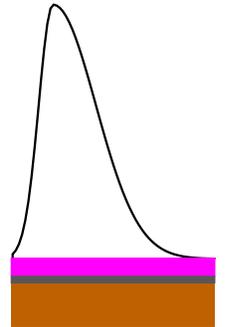

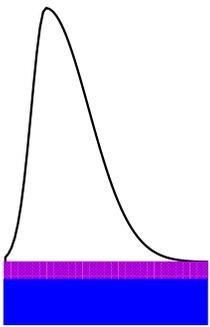

The heat flux profile in the SOL is a crucial unknown

1/0.1/10 mm Li/SS/Cu plate outperforms 10 mm Li/Mo CPS

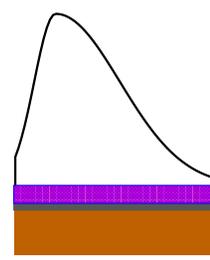

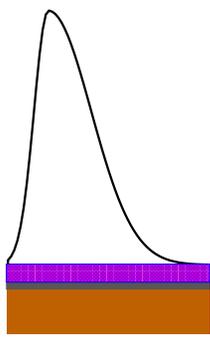

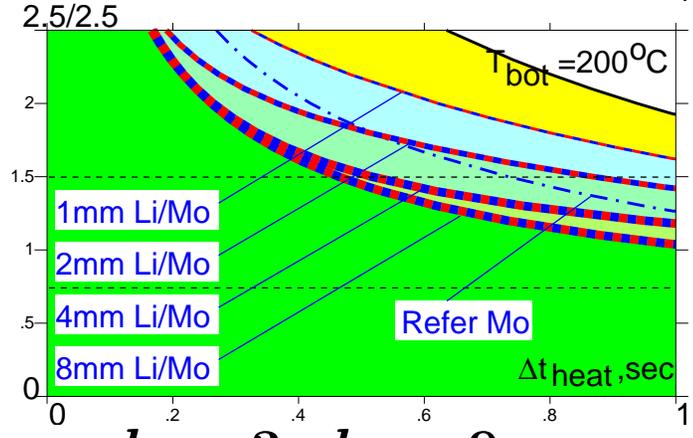

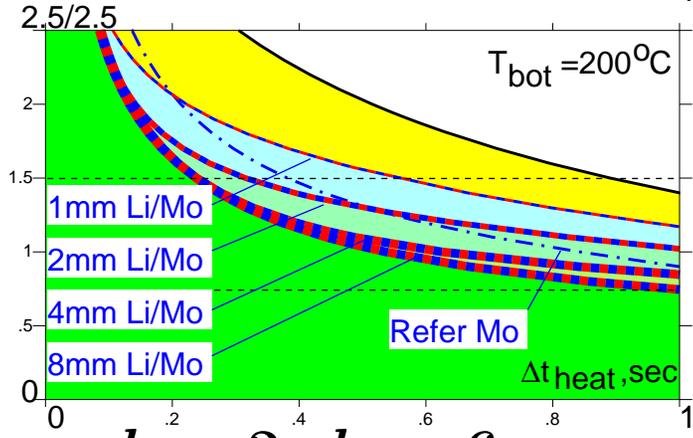

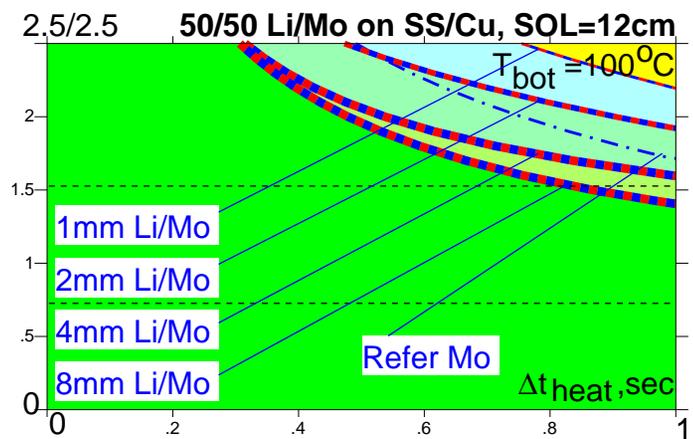

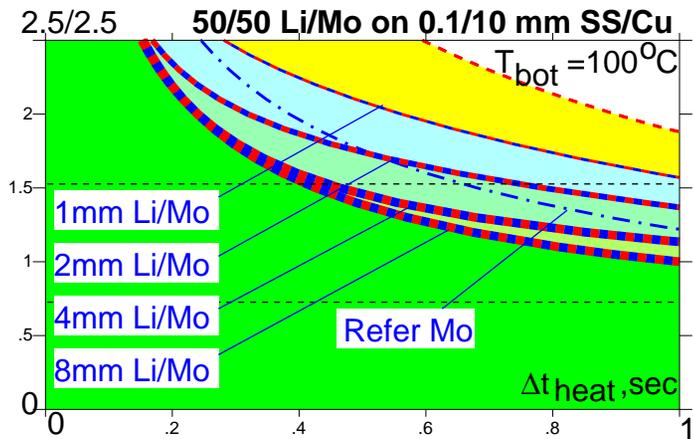

$d_i = 2, d_e = 6 \text{ cm}$

$d_i = 2, d_e = 6 \text{ cm}$

The plate also has fewer technology unknowns

1 mm Li/Mo CPS on 0.1/10 mm SS/Cu plate is the best

1 mm Li/Mo CPS on 0.1/10 mm SS/Cu is similar to T-11M, FTU

LLTP is a prototype of the Pumping Lithium Divertor, adjusted for NSTX and consistent with the strategy for ST

Neither evaporator, nor Mo sponge based “LLD”, promoted by PPPL/NSTX (May-2007 version) management, are consistent with PLD requirements

Installation of Li/SS/Cu plate will be the turning point for PPPL toward relevance to the energy R&D, lost at present

Proposed as an interim solution for NSTX, LLTP has a chance to be a longer term solution if replenishment by the Li pellets will be successful.

The role of theory is to reveal the obstacles to the progress

LLTP was suggested a year ago to PPPL/NSTX management. The answer was “NO”. It is “NO” also this year.

There is no scientific, technical or budgetary issues with LLPD. In all aspects it is superior to both “evaporator” and to so-called “LLD”.

In its countless “NO”s during the last 10 years, the current PPPL administration is self-consistent in blocking fusion development in PPPL.

**Fusion energy R&D needs Pumping LD. It is a new obsession, now
with fusion metallurgy (NHTX), which intend to drag
PPPL into fusion irrelevant research**
