# Some Background

- NSTX typically scans  $A$  and  $\kappa$  simultaneously.
- No inner gap control (at present).

- Calculations (using experimental profiles) show a reduced ideal no-wall limit when  $A$  and  $\kappa$  are increased.
- Have never done a dedicated experiment to test the experiment beta limit vs. (high)  $\kappa$  and  $A$ .

From TRANSP database of high-performance discharges

CHEASE fixed boundary + DCON

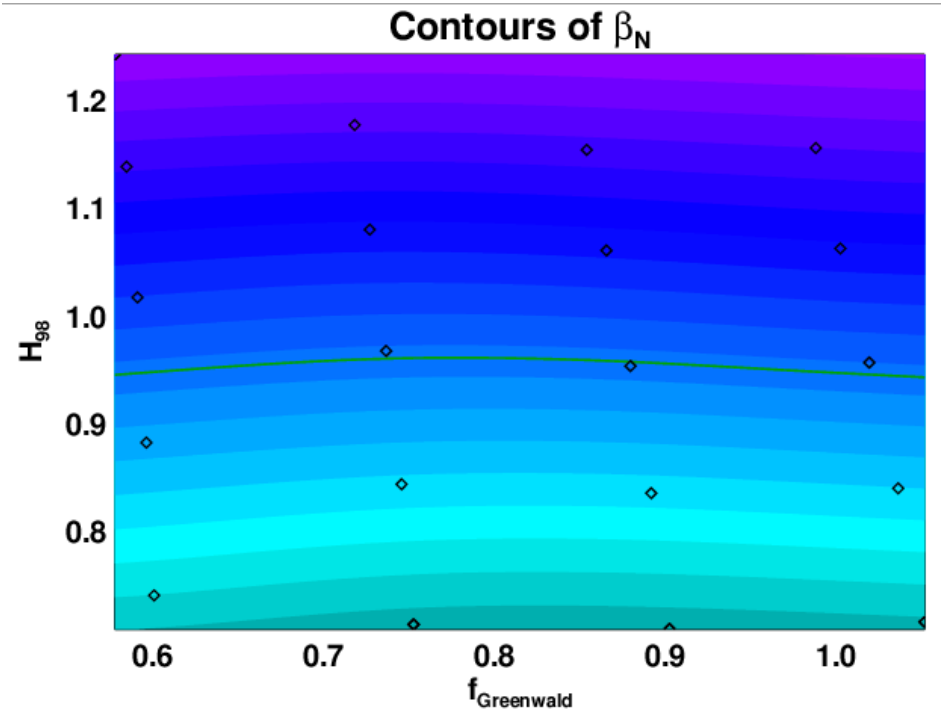

# We need to robustly sustain $\beta_N=4.5-5$ at high A and $\kappa$

- Simulations for 1.0 T, 1.0 MA,  $\kappa=2.7$ ,  $A=1.65$ , 12 MW
  - Need  $\beta_N=4.5-5$ , at  $H_{98}=1.1$ , for fully non-inductive operation.
- Scenarios with lower current and more NBCD will likely need  $A\sim 1.8$ ,  $\kappa\sim 2.9-3.0$  for more off-axis CD.

1.0 T, 1000 kA,  $A=1.65$ ,  $\kappa=2.7$ ,  $R_{\text{tan}}=[50,60,70,110,120,130]$  90 kV Beams

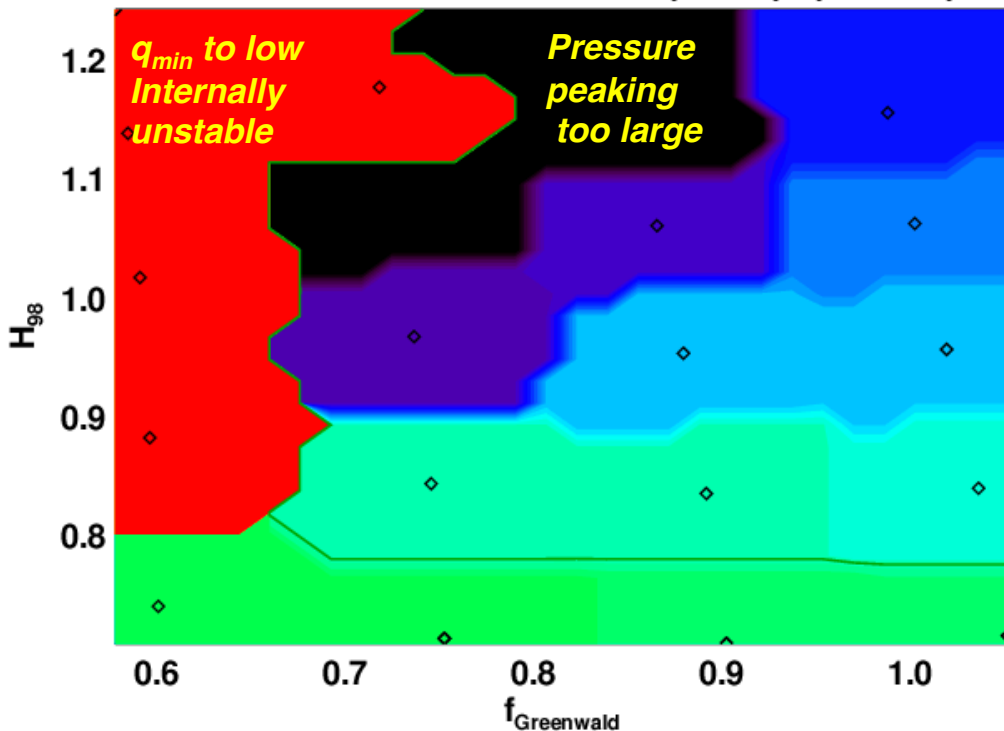

1.0 T, 1000 kA,  $A=1.65$ ,  $\kappa=2.7$ ,  $R_{\text{tan}}=[50,60,70,110,120,130]$  90 kV Beams

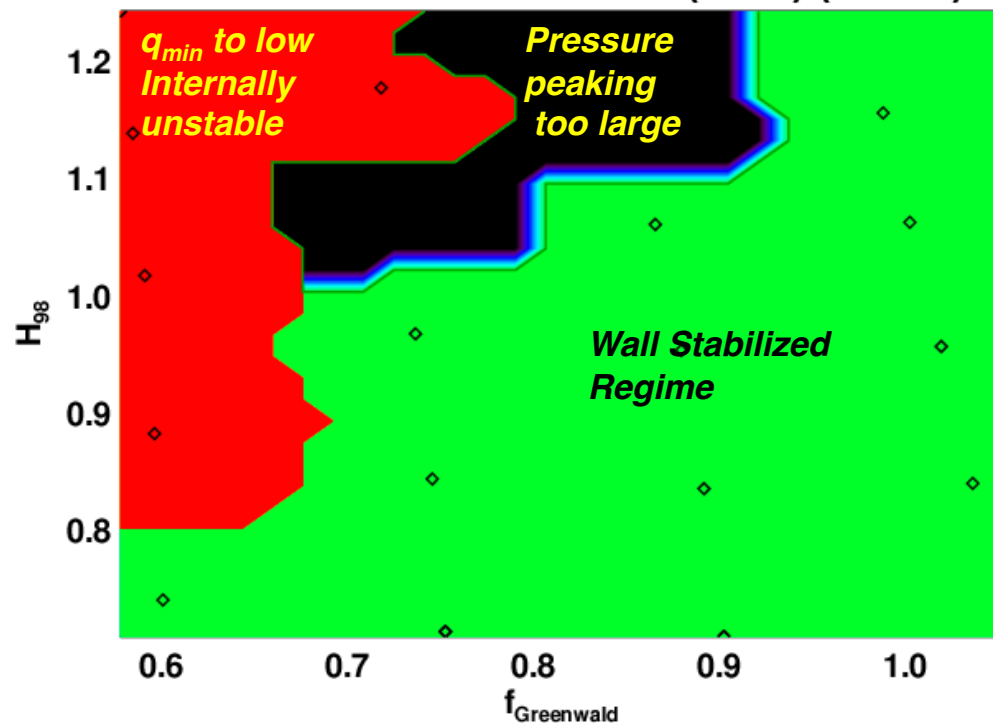

# Ideal Stability May Further Limit the Operating Space

Contours of No-Wall  $\text{atan}(\delta W/5)$  (DCON)

Contours of With-Wall  $\text{atan}(\delta W/5)$  (DCON)

**Preliminary!**

1.0 T, 1000 kA,  $A=1.65$ ,  $\kappa=2.7$ ,  $R_{\text{tan}}=[50,60,70,110,120,130]$  90 kV Beams

1.0 T, 1000 kA,  $A=1.65$ ,  $\kappa=2.7$ ,  $R_{\text{tan}}=[50,60,70,110,120,130]$  90 kV Beams

No-Wall  $\text{atan}(\delta W/5)$  (DCON)

Scan #21

With-Wall  $\text{atan}(\delta W/5)$  (DCON)

Scan #21

**Important future task: re-run with some additional fast ion diffusion to reduce the central NBCD and pressure peaking.**

**Also would be nice to improve the resolution in  $[H_{98}, f_{\text{GW}}]$  space.**

# What kind of shape changes are possible?

- Inner gap scan at fixed outer gap.
- Simultaneously increases  $A$  and  $\kappa$ .
- Maintains (nearly) constant distance to the plates and  $B_p$  RWM sensors.
- Increase the outer gap for  $\kappa=3$ ,  $A=1.75$

*All scans at 700 kA to avoid hitting PF-1A coil current limit!*

- Aspect ratio scan at fixed  $\kappa$ .
- Inner and outer gaps change at fixed plasma height

- $\kappa$  scan at fixed aspect ratio.
- Plasma height changes with fixed inner and outer gaps.

# Possible (Likely?) ASC Contributions to R11-2

- Milestone has a component related to  $n=0$  stability and control.
- Improve the vertical controller (SPG).
  - Produce a better realtime estimate of  $dZ/dt$ .
  - Optimize the derivative gain.
    - Proportional controller is the ISOFLUX algorithm.
  - If necessary, test use of RWM coils for vertical control.
- Test more advanced shape control algorithms (EK).
  - Use a fully populated “M-Matrix”
  - Use it to develop better inner- and bottom-gap control.
- Performance impact of  $\kappa$  and  $A$  (SPG).
  - Scan  $A$  at fixed  $\kappa$ , and  $\kappa$  at fixed  $A$ .
  - Use reduced input power to avoid disruptions.
  - Test confinement (and current drive) changes due to shape modifications.

## Loss of vertical control when $I_p > 0.6$

# XP Idea #1: The impact of elongation and aspect ratio on the ideal stability of ST plasmas

- NSTX has a large database of stability results with  $A < 1.55$  and  $\kappa < \sim 2.4$ .
  - High-performance NSTX upgrade scenarios will run at larger values of both these parameters.
- It is hard to scan these parameters independently in NSTX...
  - Will be even harder in NSTX-U.
  - This run is the last chance for these types of scans.
- *Relevant Milestone Text: The maximum sustainable normalized beta will be determined versus aspect ratio (up to  $A=1.7$ ) and elongation (up to 3) and compared to ideal stability theory using codes such as DCON and PEST.*
- Propose to do three types of scans (with fast RWM control off?):
  - Scan #1: Mixed  $\kappa$  & A scan at fixed outer gap (12 shots).
    - Use RFA analysis to look for passive instability.
  - Scan #2: A scan at fixed kappa (10 shots).
    - Test the disruptive  $\beta_N$  limit (use the  $\beta_N$  controller to ramp to a disrupting in a controlled way).
  - Scan #3: Kappa scan at fixed A (10 shots).
    - Test the disruptive  $\beta_N$  limit (use the  $\beta_N$  controller to ramp to a disrupting in a controlled way).
- Goals:
  - Determine if, within the achievable range of A and  $\kappa$ , there is a measurable change in global stability.
    - Compare to ideal stability theory.
  - Collect data validating the  $\beta$ -limit assumptions for NSTX Upgrade.

# XP Idea #2: MHD Stability at Very High Toroidal- $\beta$ and Normalized Current

- ST reactor designs typically assume very high toroidal  $\beta$ .
  - PPPL Pilot: 30-39%, ARIES-ST: 50%, Culham 59%
- It may be time to revisit discharge scenarios with very high  $\beta_T$ .
  - We have made many improvements in control & discharge development since these were last tried in 2005.
    - Reduced PCS latency, RWM control, Li PFC conditioning, stronger shaping, better control during the  $I_p$  ramp.
  - We have many new and important diagnostics since 2005.
    - MSE, RWM sensors, better USXR systems.
  - We may have trouble making these shots again.
    - Higher aspect ratio of NSTX-U will lower ideal stability limits.
- Propose to revisit discharges in the  $\beta_T \sim 40\%$  regime.
  - Characterize the limiting instabilities.
    - What is the maximum stable  $\beta_T$  at low  $q^*$  during the phase when  $q_{\min} > \sim 1.1$  (i.e. before kink/tearing starts).
    - Can we modify this limit via the profiles? Allow  $I_i$  to peak up to improve confinement and stability?
  - Determine to what extent recent operations improvements facilitate this regime.
  - Study disruption precursors.
    - Are disruptions detectable in advance?
