Density model is desired for reliable design and operation of feedback control

Flow diagram for density feedback control system

1

FIReTIP (NSTX tangential interferometer)

2

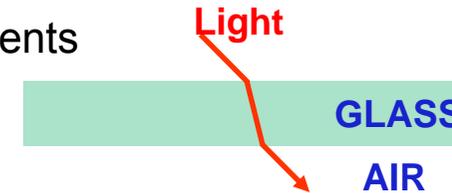

Fringe jump correction of the FIReTIP data

3

0-D modeling to design feedback controller

Far Infrared Tangential Interferometer/Polarimeter (FIReTIP) is a powerful diagnostic for many applications.

- Interferometer is the one of the refractive index measurements specialized to plasma density.

- A **line-integrated density** is obtained from phase information of the laser beam.

$$\phi = \frac{\lambda e^2}{4\pi c^2 \epsilon_0 m_e} \int_{l_1}^{l_2} n_e dl = 2.82 \times 10^{-15} \lambda \int_{l_1}^{l_2} n_e dl$$

- Methyl alcohol (CH₃OH) laser that emits **118.8μm** far infrared (= 2.52 THz) beam which is favorite for interferometers in most mid-size tokamaks.

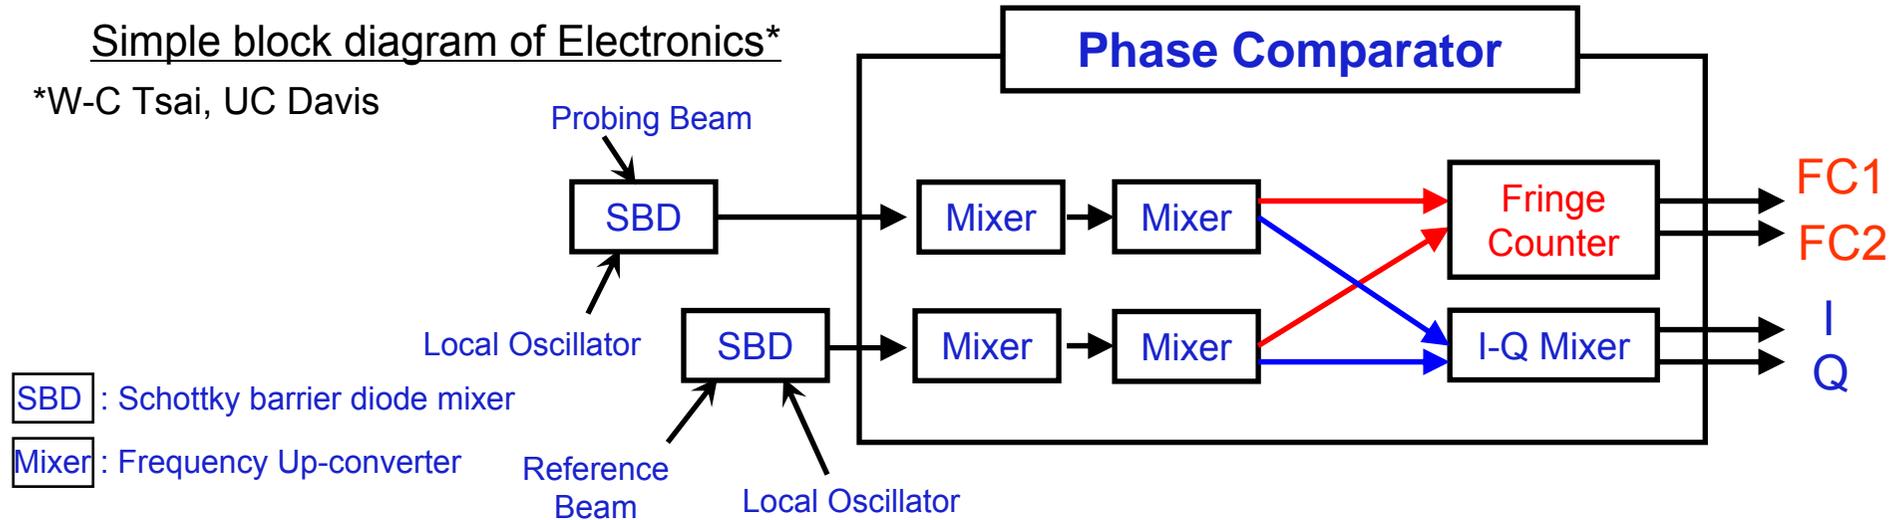

$$\text{mechanical vibration } (\propto 1/\lambda) < (\lambda, 1/f) < \text{beam-path refraction } (\propto \lambda, \nabla n)$$

- Simultaneous operation of interferometer and **polarimeter** is possible in FIReTIP.
- Frequency shift from **Stark-effect** enables high intermediate frequency (IF) as about 5MHz which is larger than twice that of common Methyl alcohol lasers.
- High bandwidth of signal up to **4MHz** is possible because of high IF and improved electronics.

Electronics in FReTIP has been recently upgraded leading to better performance especially for fast bandwidth.

Simple block diagram of Electronics*

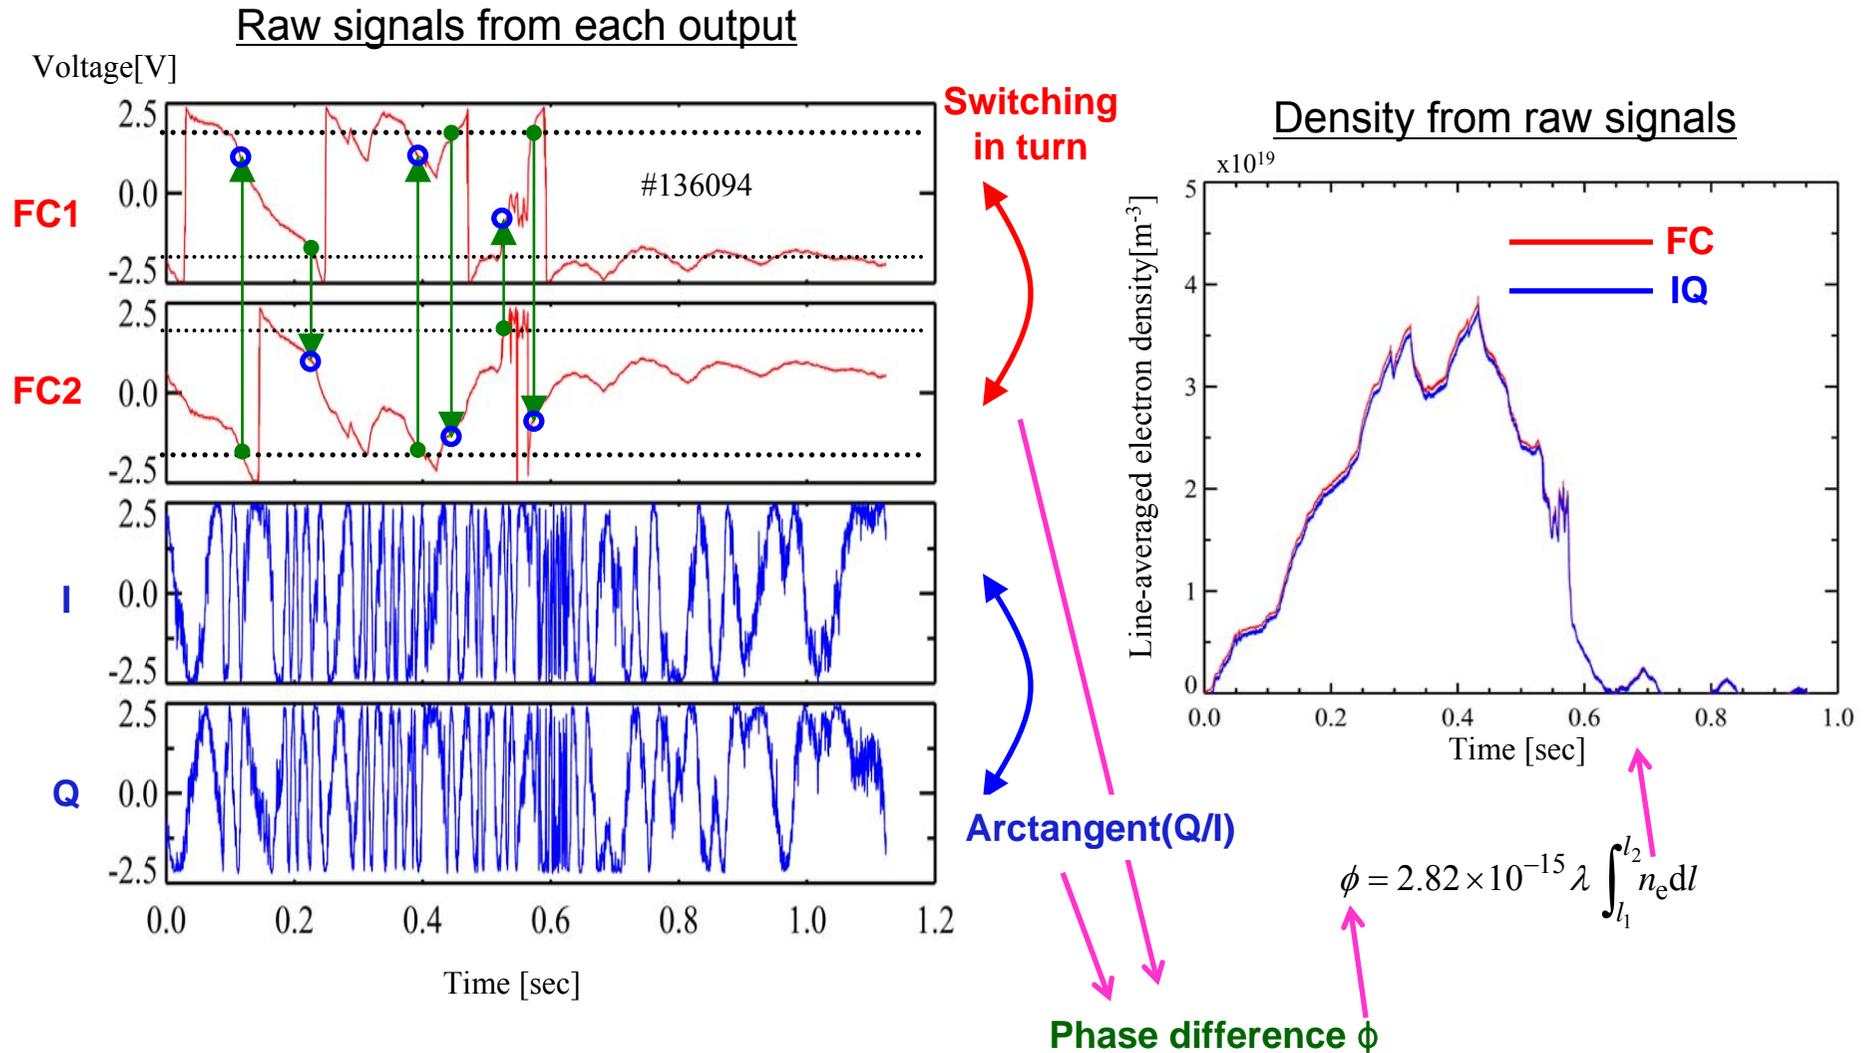

*W-C Tsai, UC Davis

Basic information about the FReTIP output signals

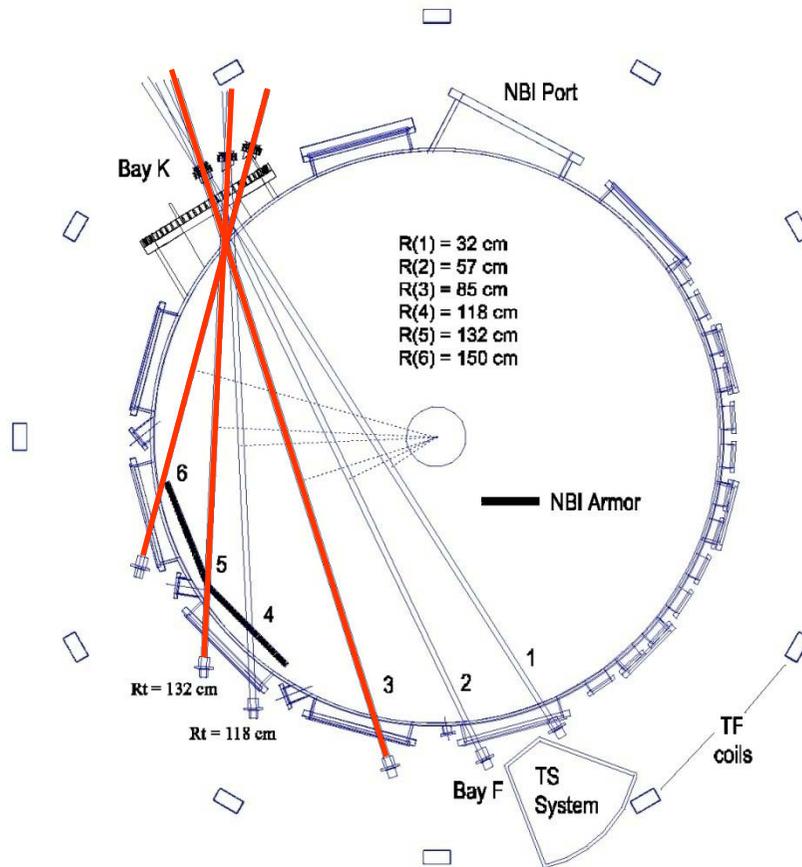

Index	FC1	FC2	I	Q
Signal ~	ϕ	$\phi (\pm 2.5V)$	$\cos(\phi)$	$\sin(\phi)$
Bandwidth	1MHz		4MHz	
Sampling rate	1Ms/s		12Ms/s	
Range	-2.5 ~ 2.5V			
Fringe Information	$8 \times 2\pi$		2π	
Remarks	Switching each other not to be limited in 5V		Arctangent to obtain ϕ	

Both density-converted signals from the fringe counter and the I-Q mixer are in good agreement with their own features.

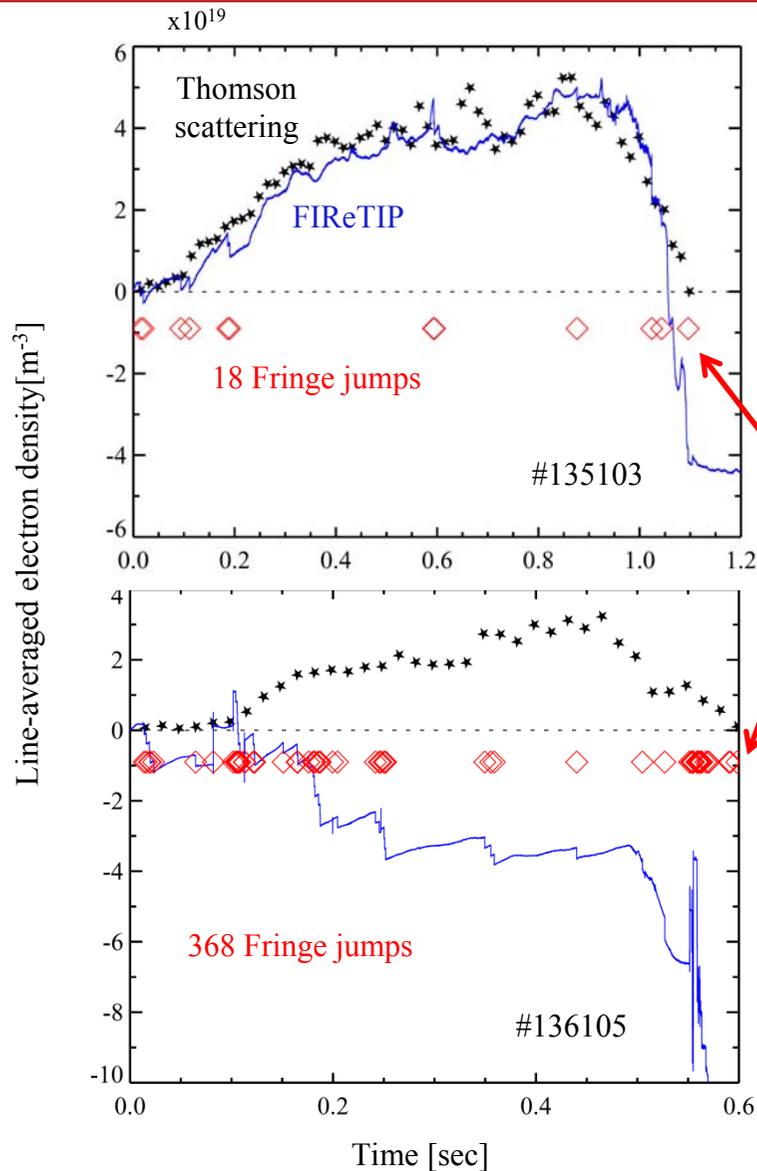

Line-integrated density up to 3 channels in mid-plane is currently being measured.

Layout of the FIRETIP beam channels.

#	Tangency Radius [cm]	One-way Path length [m]	Tag names on MDS Tree (TREE name = 'microwave')	
			FC	IQ

6	150	0.92	FC	<code>\den_firetipc7</code>
			IQ	<code>\den_fast_firetipc7</code>

Fringe Jump (FJ) Errors has been serious problems in FReTIP likely to most interferometers.

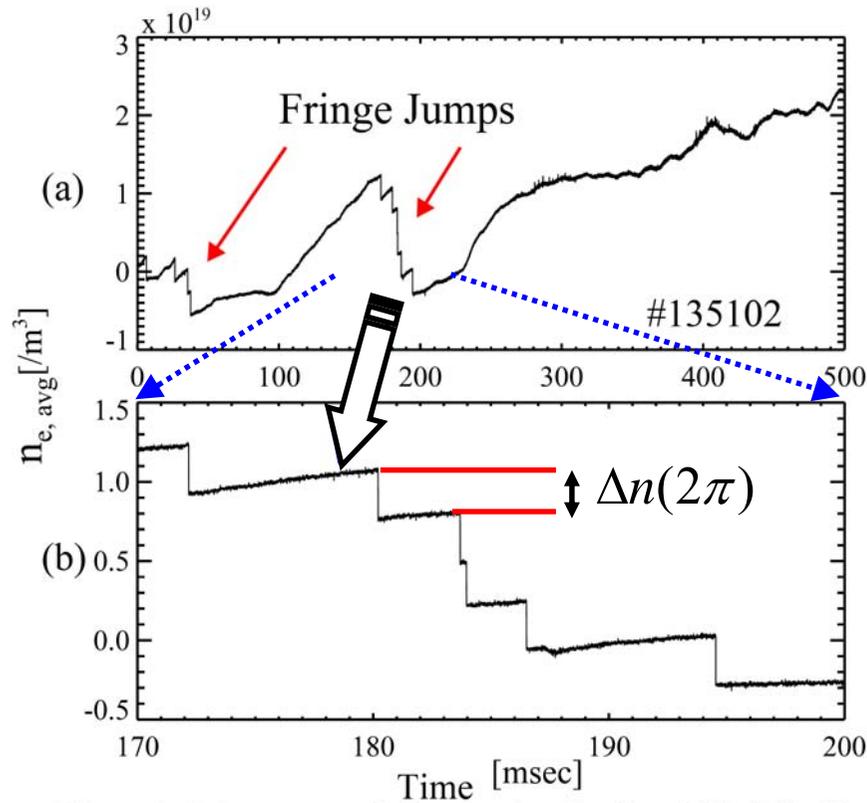

There were hundreds of discharges suffering from fringe jumps. The number of fringe jumps in those discharges are from zero to thousands, provided FReTIP system including laser power is acceptable.

Indicators of fringe jumps when they appeared.

Apparently, the whole waveform seems to be more absurd as the number of FJ increases. Even in some discharges with only several fringe jumps the difference between data from FReTIP and Thomson scattering diagnostics is quite distinct so we are not able to use the original data.

Fringe Jump Errors in FReTIP has typical characteristics.

They take place in a few **microseconds** usually, and up to a couple of tens microseconds. Most of them have typical jumps with variation of **one-fringe** equivalent voltage or density.

$$\Delta n_{e, \text{avg}} = \frac{4\pi c^2 \epsilon_0 m_e}{\lambda e^2 L} \Delta \phi \quad \leftarrow \quad \begin{array}{l} \Delta \phi = 2\pi \\ L = 6.18 [m] \\ \text{For Channel 1} \end{array}$$

$$\approx 3.03 \times 10^{18} [m^{-3}]$$

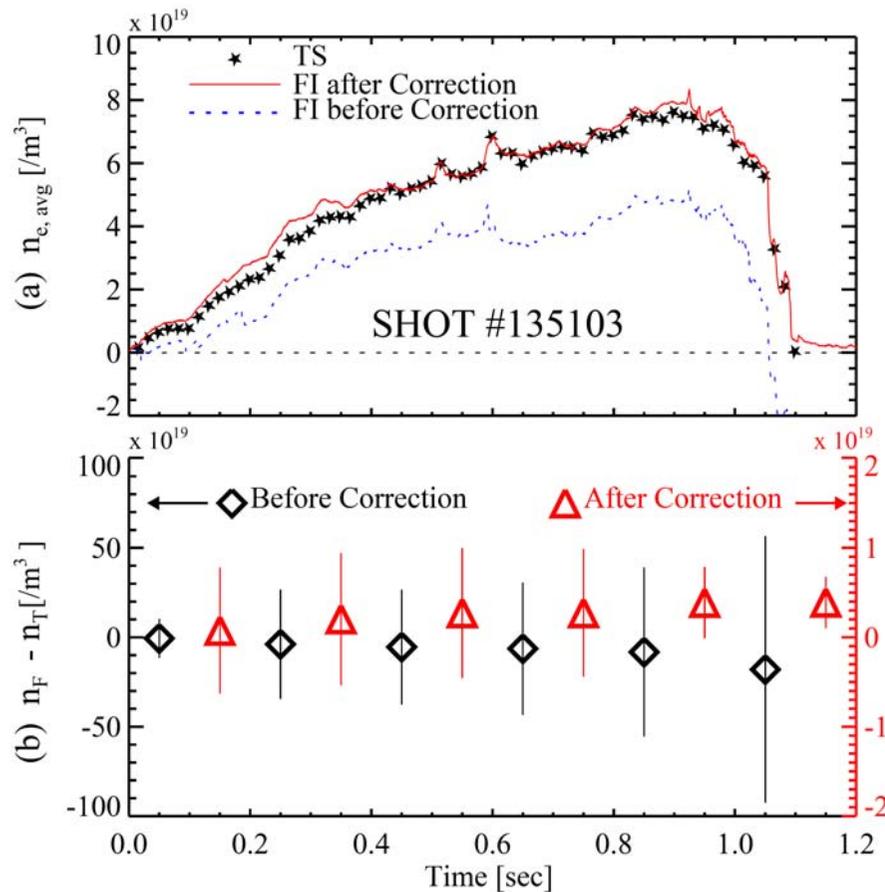

$$\frac{\Delta n_{e, \text{avg}}}{\Delta t} \approx \frac{3 \times 10^{18} [m^{-3}]}{10 [\mu\text{sec}]}$$

$$= \frac{3 \times 10^{22} [m^{-3}]}{100 [m\text{sec}]}$$

Obviously not a plasma activity

Fringe Jump Errors were suppressed by post-processing of stored data.

Fringe jump corrected data compared with those of Thomson scattering diagnostics

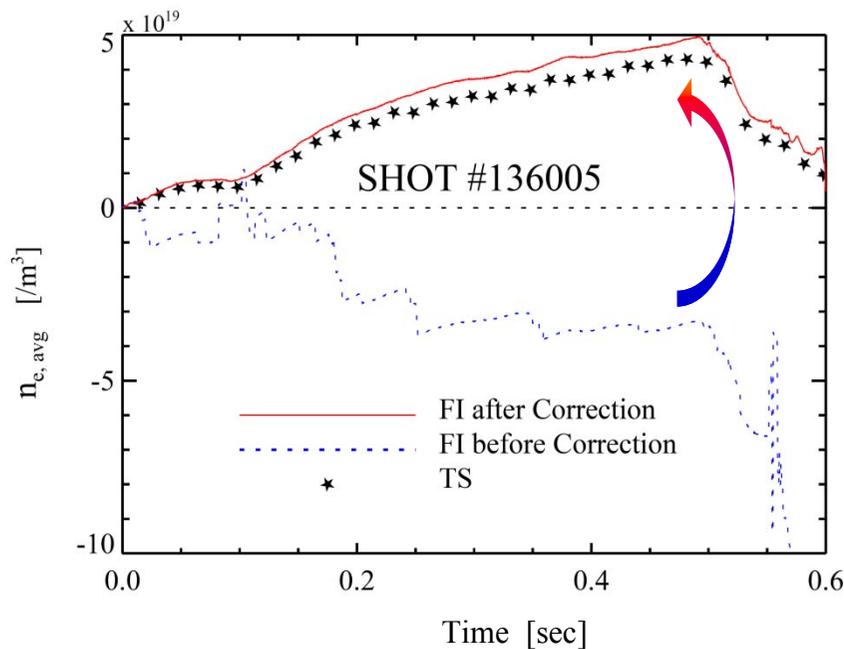

By applying the algorithm, corrected FReTIP data is compared with Thomson Scattering data which is reproduced along the beam path of FReTIP CH.#1.

(a) An example of full waveforms of each case: The corrected data show very **good agreement** with those of Thomson scattering

(b) Averages and deviations of the discrepancies from most shots after July 2009: They are distinctively reduced after correction .

This algorithm works even in cases of up to a few hundreds of fringe jumps event.

Fringe jump corrected data compared with those of Thomson scattering diagnostic : FI means FReTIP data, TS Thomson scattering diagnostic data respectively.

368 Fringe jumps were reported and suppressed.

Even in this case of huge errors, corrected data has quite reasonable value compared with data without correction in dashed blue line. The correction algorithm has high opportunity to make the data reliable in most situations.

This algorithm has been routinely working since FY2010 and it is archiving the corrected FReTIP data automatically in most cases without distinct problems.

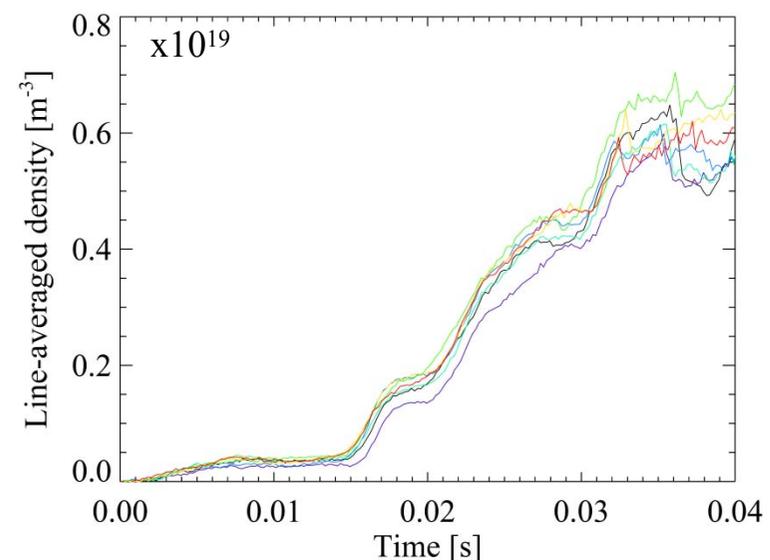

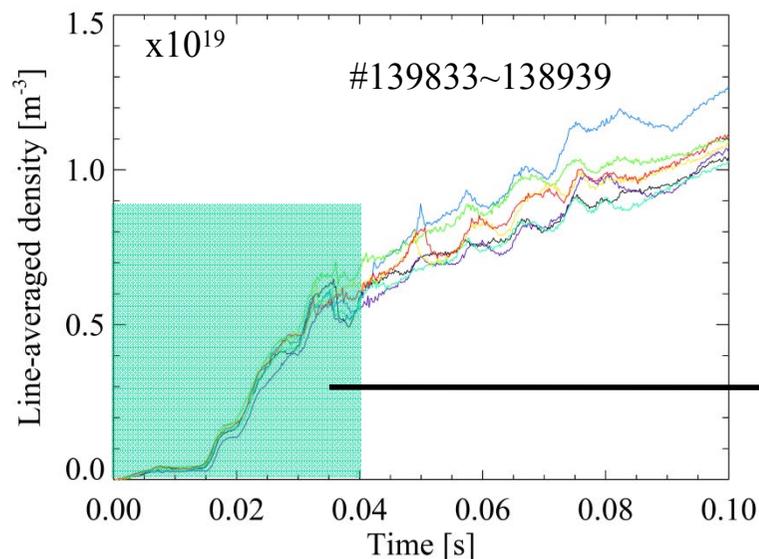

FIReTIP data is being archived through PCS digitizer for real-time density control.

#	Tangency Radius [cm]	One-way Path length [m]	Tag name on MDS Tree (TREE name = 'microwave')	
n (~ CH3)	85	2.64	FC	\n

CH.3 Fringe counter (FC) data is being used after the fringe jump error correction and this works good as compared with the original signals.

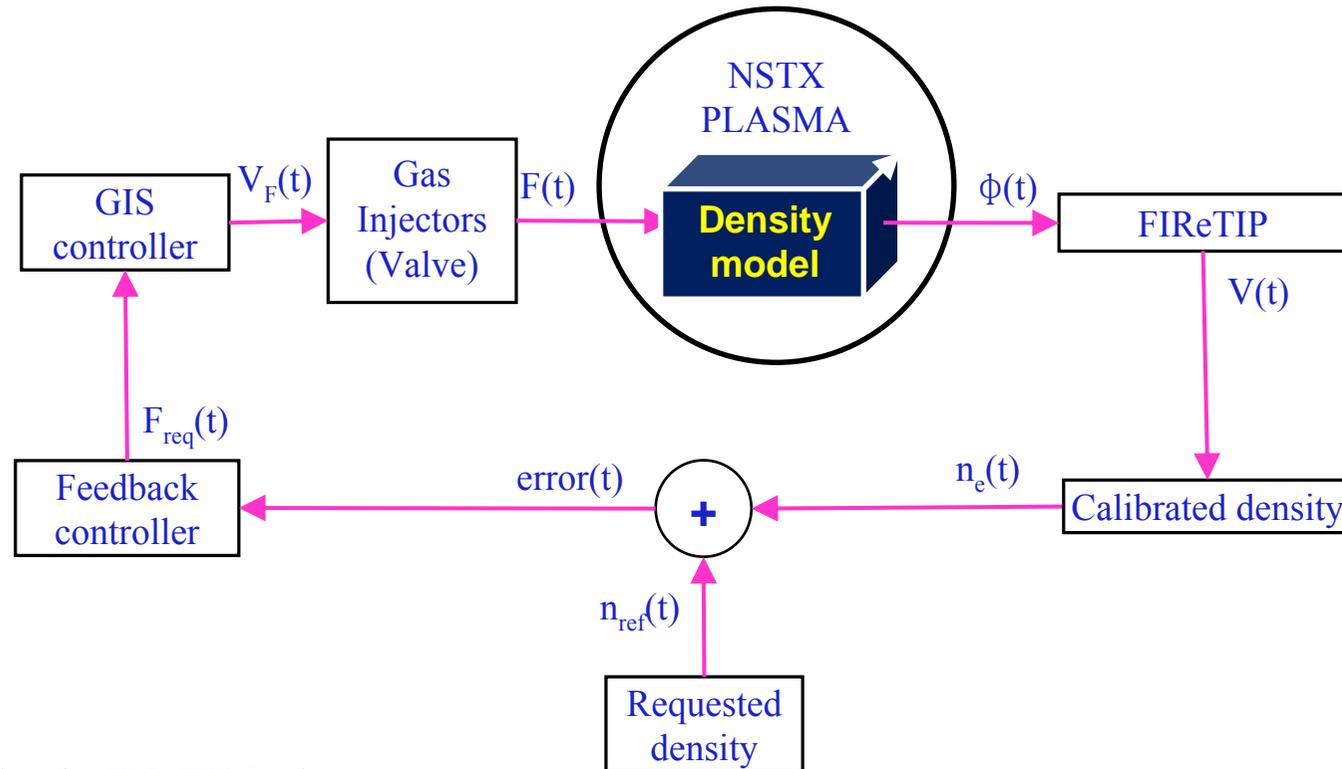

5kHz digitizer is fast enough to control gas injection valves which operate at least in every 2ms.

PCS algorithm for density control has to be prepared.

Density model is desired for reliable design and operation of feedback control system

3

ϕ : phase information for FReTIP [rad]

V : phase-corresponding analog voltage output [V]

n_e : Calibrated density from FReTIP output [m^{-3}]

n_{ref} : Requested density at certain time t [m^{-3}]

$\text{error}(t)$: $n_{\text{ref}}(t) - n_e(t)$ [m^{-3}]

F_{req} : requested flow rate according to the error

V_F : voltage input to gas injector valve for requested flow rate

F : Gas flow input [s^{-1}]

0-D global rate equations : Fielding's model

$$\text{Ion : } N_i \quad \frac{dN_i}{dt} = -\frac{N_i}{\tau_i} + \xi N_s N_i S \quad \text{Fielding(1978)}$$

$$\text{Wall Neutral : } N_w \quad \frac{dN_w}{dt} = -\phi \frac{N_i}{\tau_i} \frac{\sigma}{A} N_w - \frac{N_f}{\tau_f} \frac{\sigma}{A} N_w + f\phi \frac{N_i}{\tau_i} (1-\beta) + f \frac{N_f}{\tau_f} (1-\beta)$$

$$\text{Fast Neutral : } N_f \quad \frac{dN_f}{dt} = -N_f N_i S - \frac{N_f}{\tau_f} (1-\beta) + N_s N_i X + \phi\beta \frac{N_i}{\tau_i}$$

$$\text{Slow Neutral : } N_s \quad \frac{dN_s}{dt} = -N_s N_i S - N_s N_i X + \phi \frac{N_i}{\tau_i} N_w \frac{\sigma}{A} + \frac{N_f}{\tau_f} N_w \frac{\sigma}{A} + \psi$$

A : plasma-wall interaction area

f : wall-area fraction without gettering

ξ : ionizing fraction in SOL

ϕ : escaping-ion fraction across SOL

τ_i : ion confinement time

τ_f : fast neutral confinement time

β : reflection coefficient on the wall

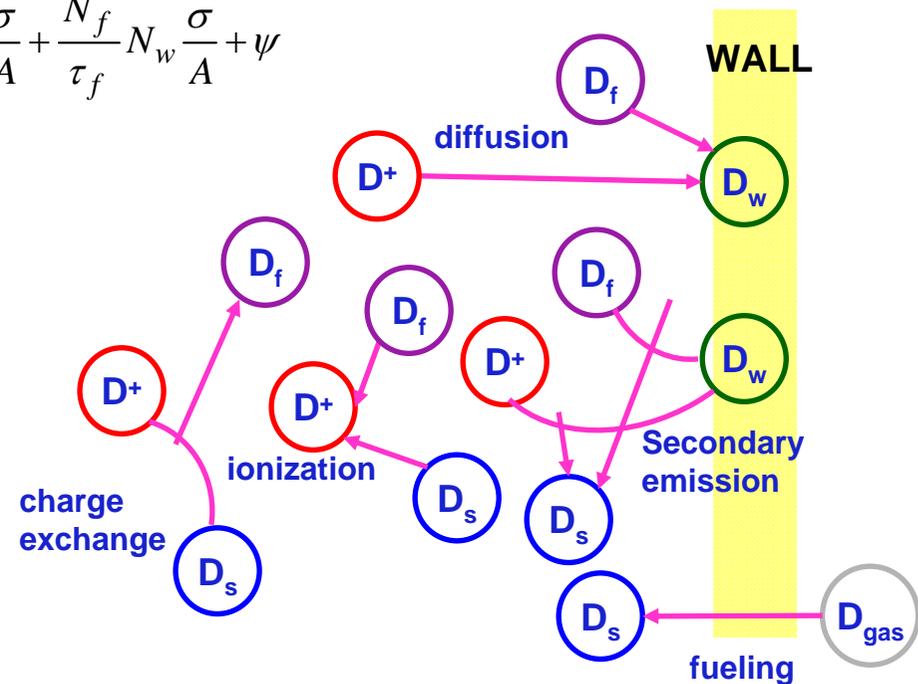

σ : cross-section for secondary emission on the wall

S : ionization rate coefficient

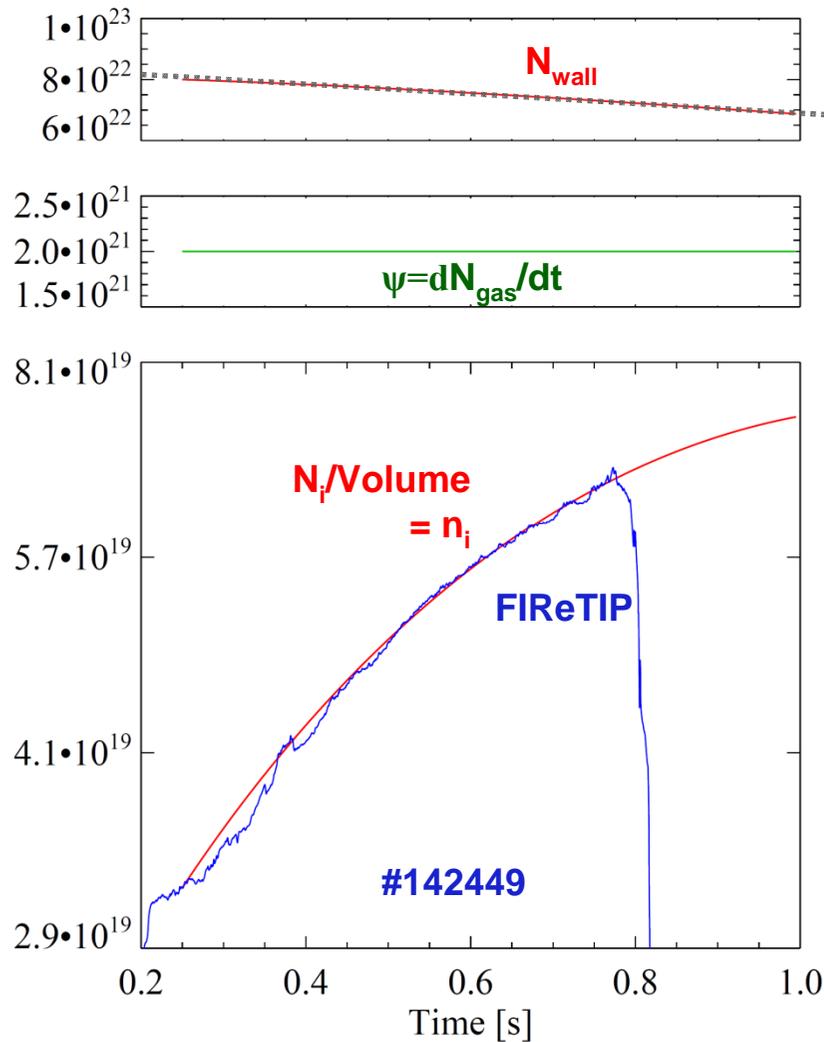

X : charge-exchange rate coefficient

ψ : external gas input [s^{-1}]

Schematic diagram

The global density shows good agreement with FIRETIP measurement with monotonic density increase.

Wall outgassing

$$dN_{\text{wall}}/dt \approx -2.3 \cdot 10^{22} \text{ (equiv. } \sim 350 \text{ Torr}\cdot\text{liter/s)}$$

↑ x100

$$dN_{\text{gas}}/dt \approx 2 \cdot 10^{21} \text{ (equiv. } \sim 30 \text{ Torr}\cdot\text{liter/s)}$$

External gas injection

Enormous WALL OUT-GASSING!!

$$N_{\text{wall},0} \approx 8 \cdot 10^{22} : \text{initial wall inventory}$$

$T_i = 0.8 \text{ keV}$ ion temperature

$$\tau_f = 7.7 \mu\text{s} : \text{fast neutral confinement time} \quad \tau_f \approx \frac{a}{v_f} = a \sqrt{\frac{2T_i}{m_i}}$$

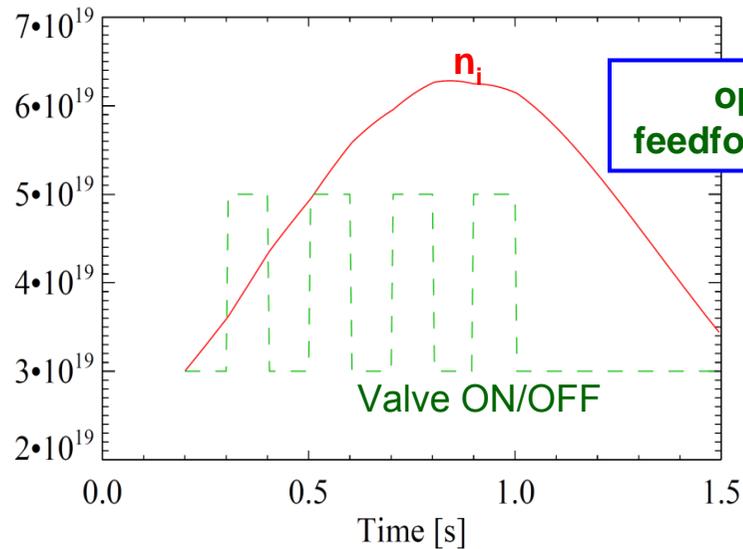

$\chi_i \approx 4 \text{ m}^2/\text{s}$: ion thermal diffusivity

$$\tau_i \approx 100 \text{ ms} : \text{ion confinement time} \quad \tau_i \approx \frac{a^2}{\chi_i}$$

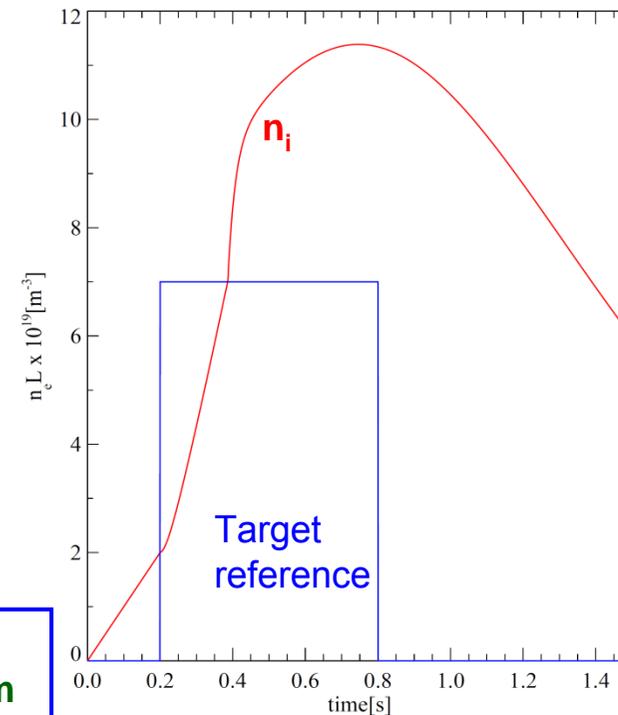

$\tau_i \approx 150 \text{ ms}$: more practical

$A [\text{m}^2] \approx 20$: Plasma-wall interaction

The plasmas in this status are not controllable because of high wall outgassing.

open- loop
feedforward system

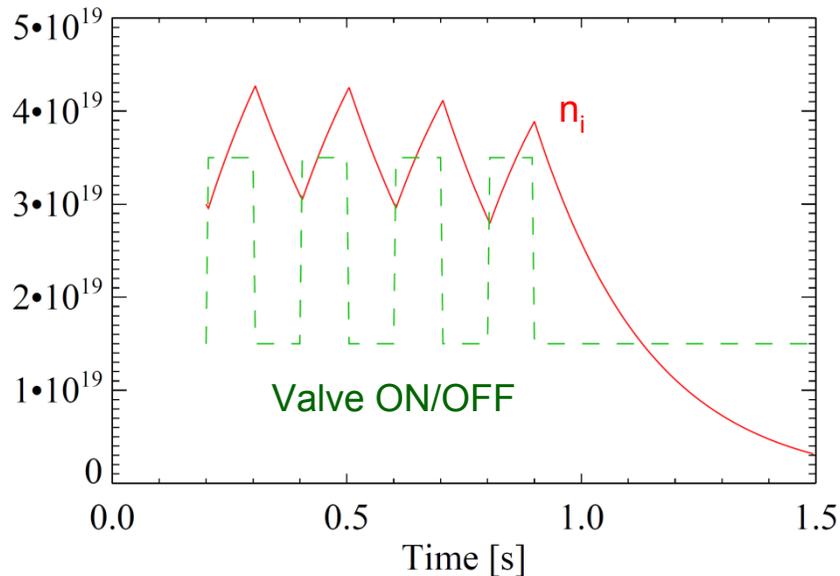

closed- loop
feedback system

$N_{\text{wall},0} \approx 8e22$: initial wall inventory

Same parameters used for measured density data are applied and do fail in feedback calculation as well as in the pre-programmed one.

Modification of wall inventory is required to control plasma by active gas injection.

$$\tau_i \approx \frac{a^2}{\chi_i}$$

$\chi_i \approx 4 \text{ m}^2/\text{s}$: ion thermal diffusivity
 $\tau_i \approx 100\text{ms}$: ion confinement time

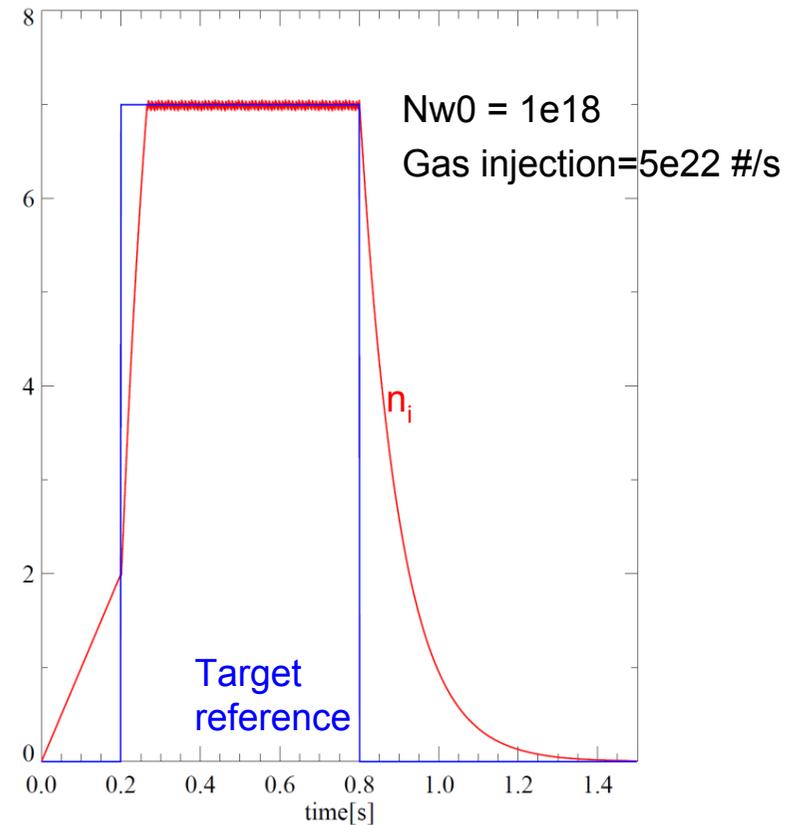

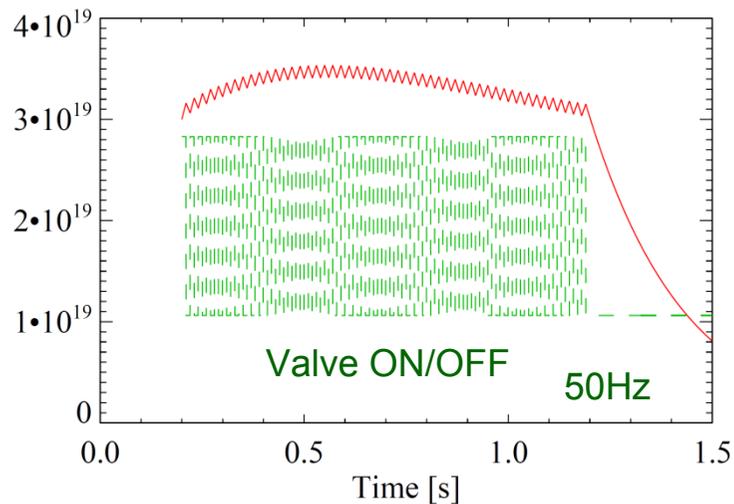

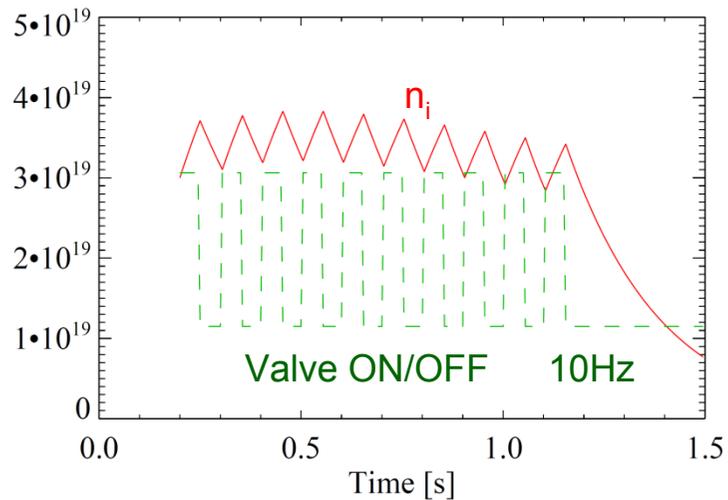

$8.5\text{e}22$
 \downarrow
 $N_{\text{wall},0} \approx 5.0\text{e}22$: ion confinement time

Gas flow rate $\approx 1.0\text{e}22$: $\sim 150\text{Torr}\cdot\text{liter}/\text{s}$

300 significant reduction
 \downarrow
 $N_{\text{wall}}/\text{dt} \approx -6.4 \times 10^{21}$ (equiv. $\sim 90\text{Torr}\cdot\text{liter}/\text{s}$)

Reduced initial wall inventory and enhancement of gas flow rate lead to success in feed-forward simulation. About 2/3 of initial wall inventory results in 1/3 outgassing from the previous calculation because of the non-linear model.

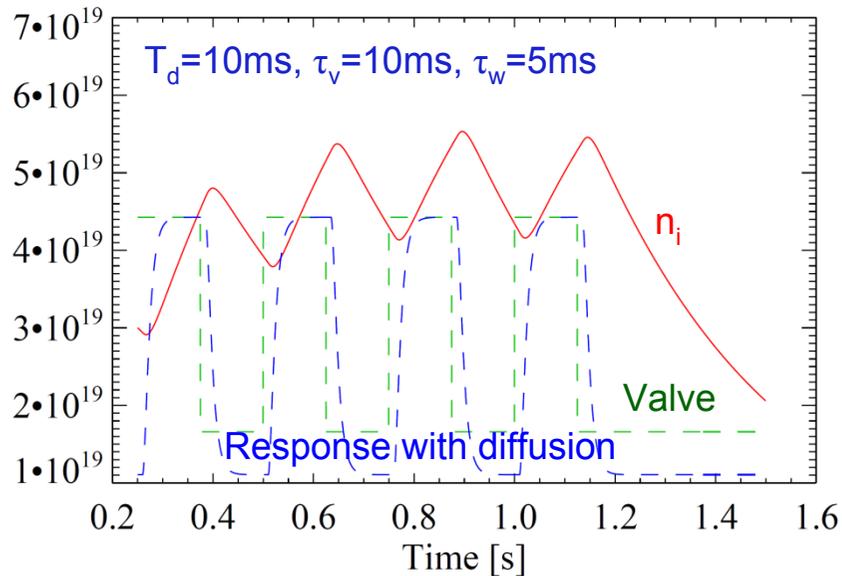

In this simple model, plasmas react rapidly upon the valve signals so that it can not be considered as realistic behaviors.

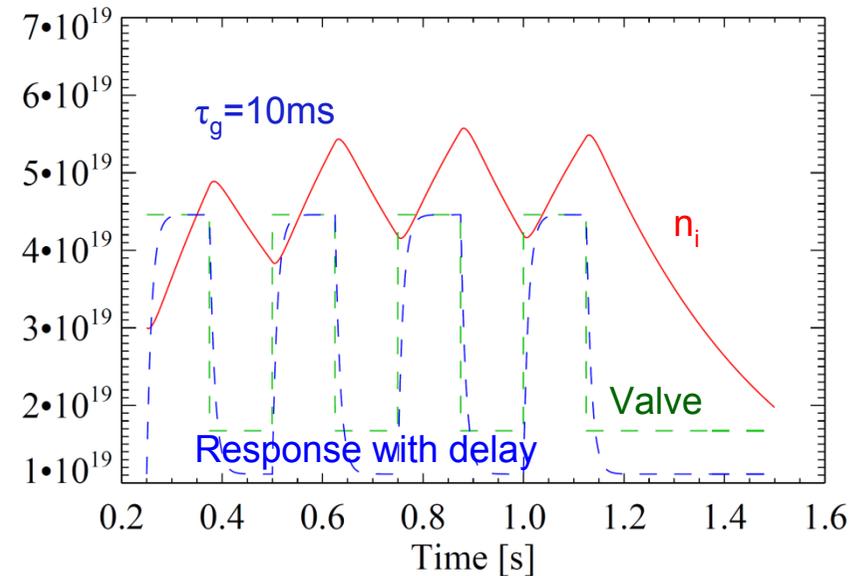

Simulations both of feed-forward up to 50Hz valve modulation and feedback give good results. These successive results, however, does not reflect the practical experiments.

2 Different approaches for diffusion or delay effects on gas fueling were tried.

Wong(1992)

Maddison(2006)

$$\Psi_{diff}(t) = \Psi(t) * y(t) \quad (\text{Convolution}) \quad \Psi_{diff}(t) : \text{Fueling rate [\#/s]}$$

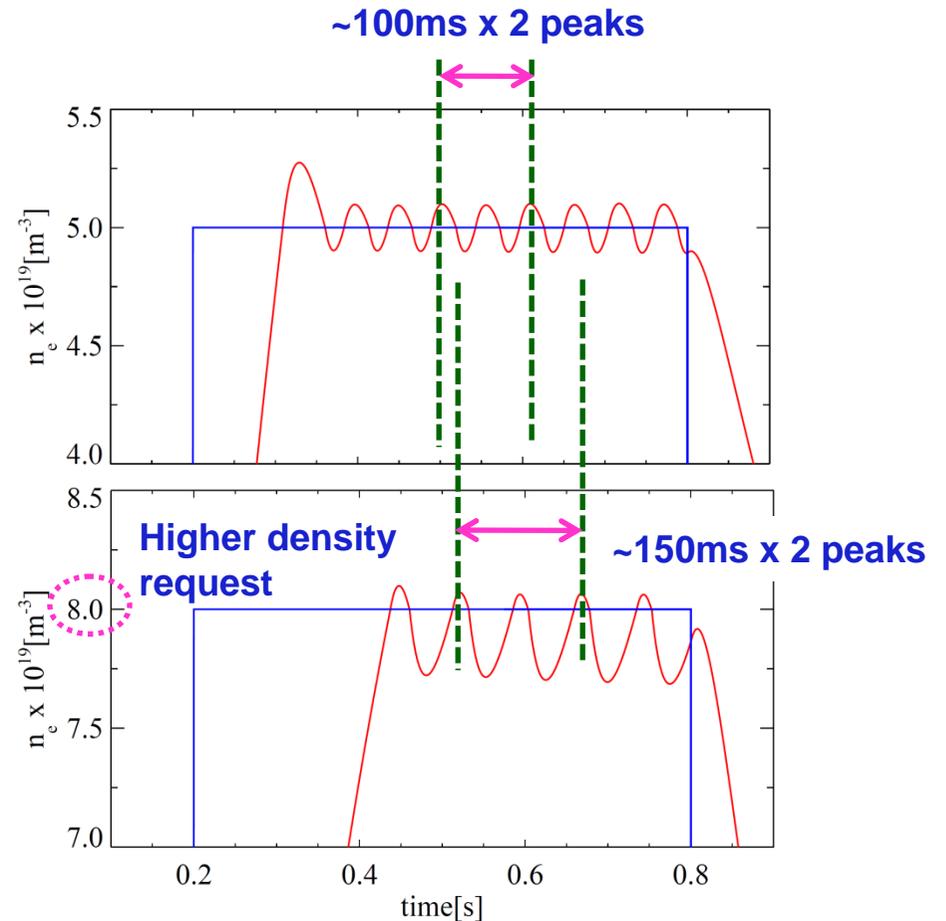

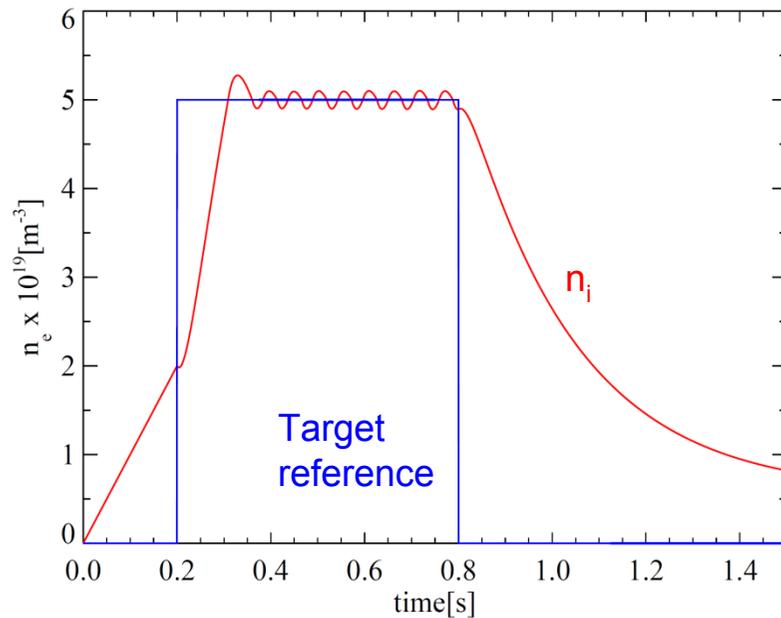

$$= \Psi(t) \times \int_{T_d}^t \frac{\exp(-|t'-T_d|/\tau_v) - \exp(-|t'-T_d|/\tau_w)}{\tau_v - \tau_w} dt' \quad : t > T_d$$

$$= \Psi(t) \times \frac{\tau_w \exp(-|t-T_d|/\tau_w) - \tau_v \exp(-|t-T_d|/\tau_v) - \tau_w \exp(-T_d/\tau_w) + \tau_v \exp(-T_d/\tau_v)}{\tau_v - \tau_w}$$

$$\Psi_{diff}(t) = e^{-t/\tau_g} \int_0^{t'} \frac{e^{t'/\tau_g}}{\tau_g} \Psi(t') dt'$$

Although each approach has different equation, both are very similar each other only with minor discrepancy of waveforms, provided with the same delay time.

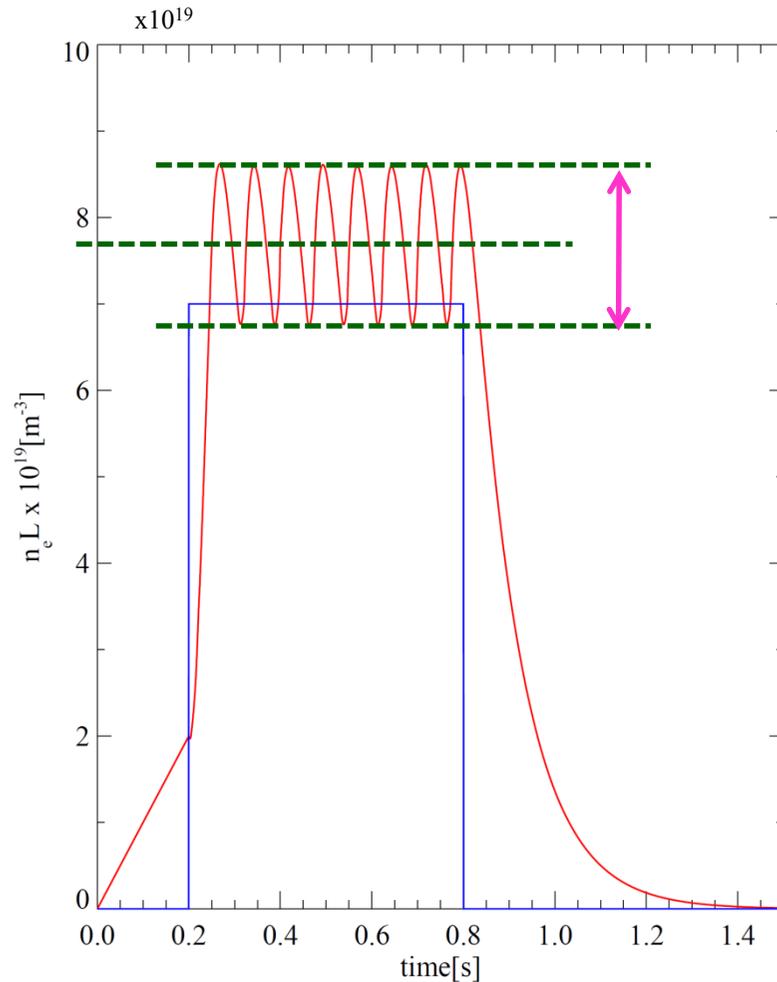

Delay-introduced reaction

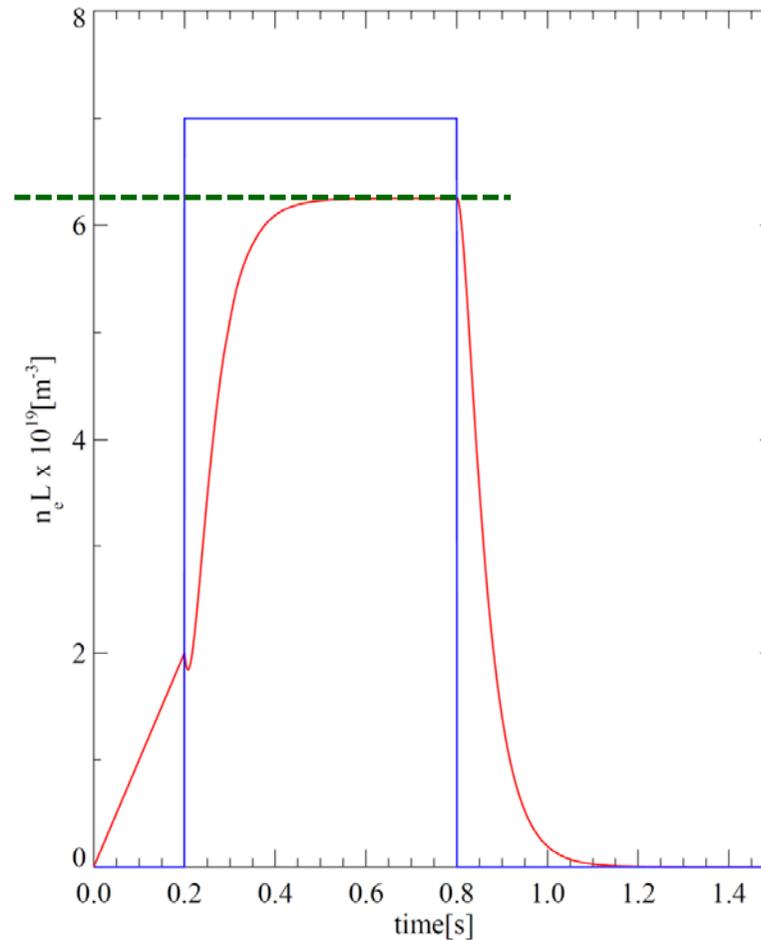

- $Nw0 = 3e22$
- $dNw/dt \sim 2.89e21 \text{ s}^{-1} \sim 20 \text{ Torr-liter/s}$
- Gas injection = $2e22 \text{ s}^{-1} \sim 300 \text{ Torr-liter/s}$
- Response delay time = 20ms

20ms response delay leads to 50~75 ms-oscillation period of density

Previous approach with fixed flow rate and fast response to the error is stable, but not accurate.

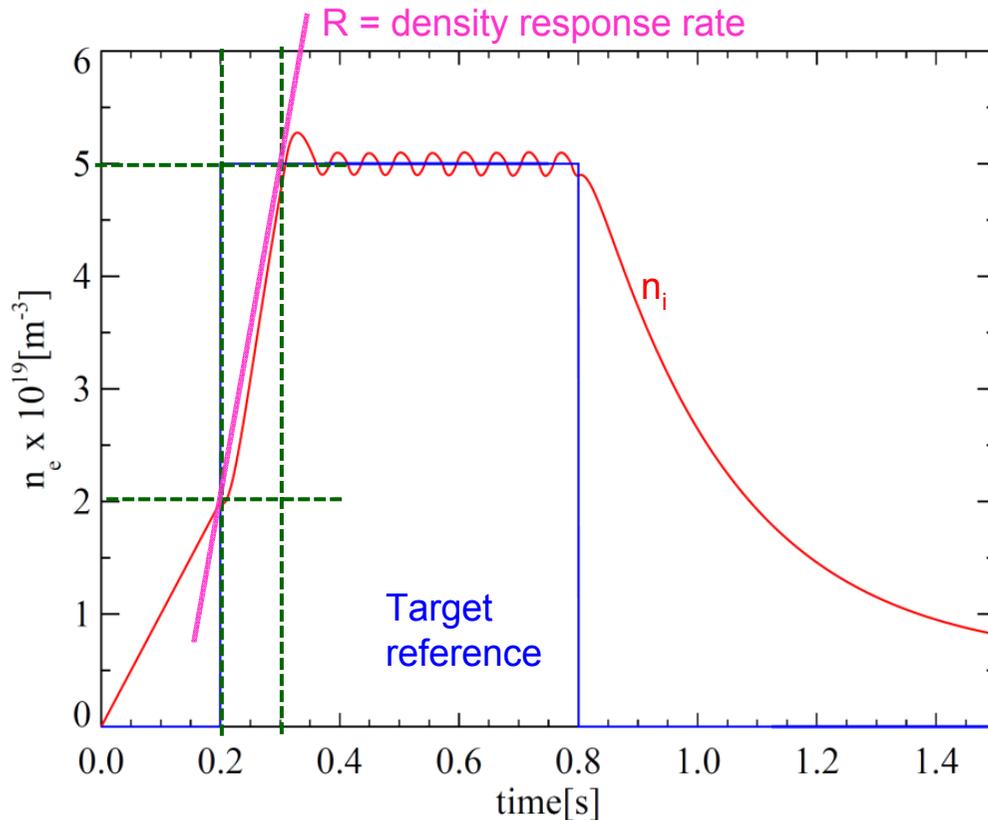

- $Nw_0 = 1e18$
- Gas injection = $10e22 \leftarrow 5e22 \text{ \#}/\text{s}$
- Delay time = 20msec

- $Nw_0 = 1e18$
- Gas injection = $5e22 \text{ \#}/\text{s}$
- Ion confinement time 50ms \leftarrow 100ms

Design of simple proportional feedback control algorithm

Previous approach was stable but not accurate because of fixed response.

Only ON/OFF time modulation is assumed to be applicable for gas injection control with fixed flow rate ($=2 \times 10^{22} \text{s}^{-1} \sim 300 \text{ Torr}\cdot\text{liter/s}$).

$$R = \frac{(5 - 2) \times 10^{19} [\text{m}^{-3}]}{(0.3 - 0.2) [\text{s}]} = 3 \times 10^{20} [\text{m}^{-3} \text{s}^{-1}]$$

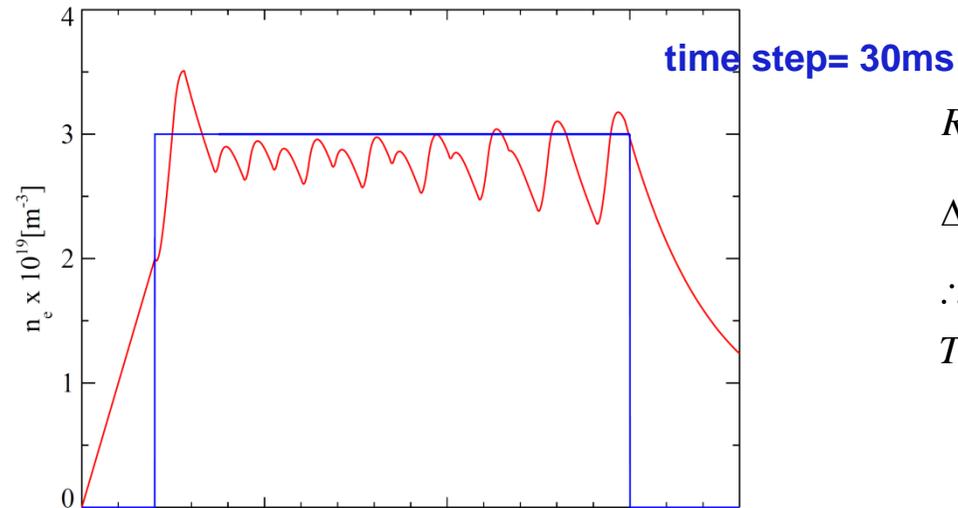

$$\Delta n = n_{ref} - n$$

$$\therefore [\Delta n / R] = \text{m}^{-3} / (\text{m}^{-3} \text{s}^{-1}) = \text{s}$$

Valve opening duration

- $Nw_0 = 3e22$
- $dNw/dt \sim 2.89e21 \text{ s}^{-1} \sim 20 \text{ Torr}\cdot\text{liter/s}$
- Gas injection $= 2e22 \text{ s}^{-1} \sim 300 \text{ Torr}\cdot\text{liter/s}$
- Response delay time = 20ms

Proportional controller is not the best for valve modulation

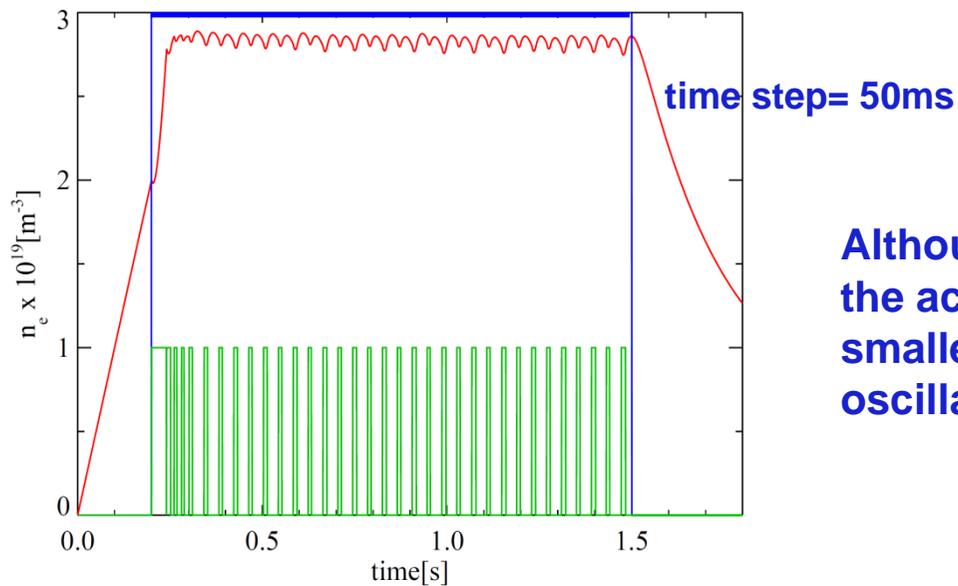

$$R = \frac{(5 - 2) \times 10^{19} [\text{m}^{-3}]}{(0.3 - 0.2) [\text{s}]} = 3 \times 10^{20} [\text{m}^{-3} \text{s}^{-1}]$$

$$\Delta n = n_{ref} - n$$

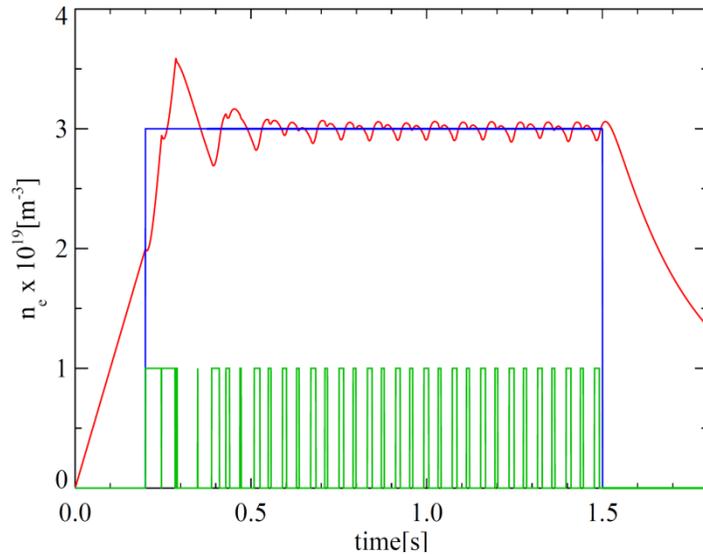

$$\therefore G = 1/3 \times 10^{20} \times 1.5$$

$$T_{open} = G \Delta n$$

Although This controller does not guarantee the accuracy for the target value although smaller time step can provide smaller oscillation of density.

PI controller can provide density close to target but there is still oscillations.

time step= 30ms

target density= 3×10^{19}

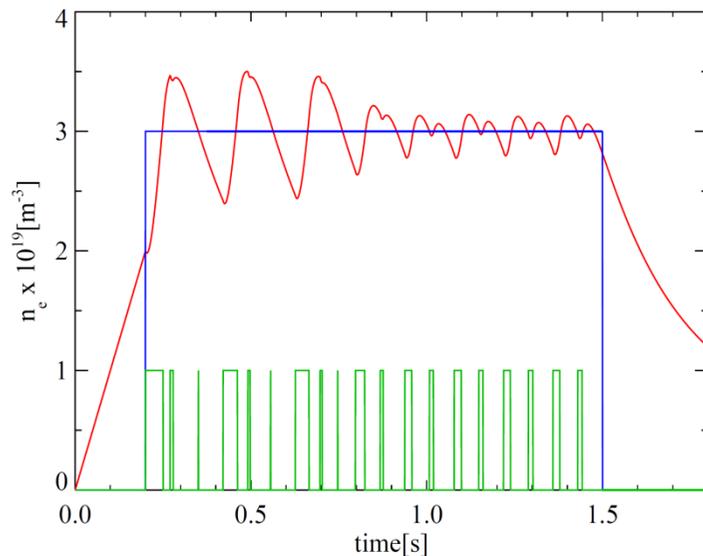

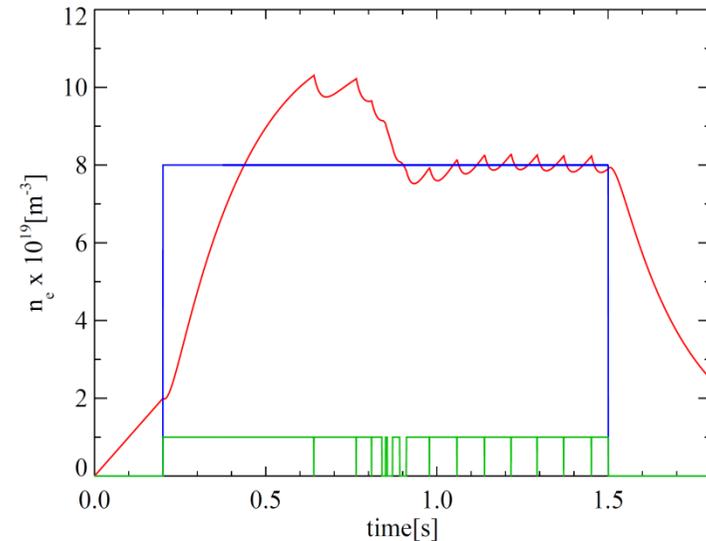

$$\Delta n = n_{ref} - n$$

$$G_P = 1/3 \times 10^{20} \times 1.5$$

$$G_I = G_P \times 0.02$$

$$T_{open} = G_P \Delta n + G_I \int \Delta n$$

target density= 8×10^{19}

time step= 50ms

Valve time modulation inherently leads to oscillation even if the PI controller has been tried. Flow rate control by valve orifice variation seems to be desired for better control performance

Summary and conclusion

- Recently upgraded electronics from UC Davis enables the fast signal processing and this leads to the easy characterization and suppression of fringe jumps in FIREtIP.
- Fringe jump errors are automatically corrected after almost every shot, provided with normal status of FIREtIP.
- The algorithm is applicable to the FIREtIP signals digitized by PCS for real-time density control which are archived together.
- Preliminary density model based on that of Fielding tried and it shows good agreement provided the parameters are adjusted.
- Using feedback control, density is achieved in a desired value without huge dependence on other parameters when reduced wall degassing is guaranteed.
- Global density model has been established for NSTX plasmas and preliminary study with that model has been tried. For the simple system, the valve opening-duration modulation was tried. The proportional controller does not provide good performance. PI controller turned out to be better in terms of accuracy. Both system can not lead to full equilibrium because the modulation. Further experiments such as feed-forward density controls are required to obtain proper parameters. New approach is required as well if it is to be applied for NSTX start-up density control.
