Is the ST a viable route to fusion?

The ST has a number of promising features, eg
simpler construction than conventional tokamaks
good confinement,
low halo currents,
high density operation,
good stability (particularly at high elongation).

But questions remain to be addressed:

How does confinement scale?

Are there options for handling the exhaust?

What is the pressure limit ($\beta_N \sim 6$ achieved on START and NSTX)?

Can we demonstrate non-inductive current drive (and start-up)?

Fundamental plasma physics at high $\beta \sim 1$

We are entering an exciting era

The role that the ST has to play in the development of fusion should
become clear in the next few years

- Two future ST devices to consider:
 - **1 GW(e) ST Power plant (STPP)**
 - **ST Component Test Facility (CTF)** to complement IFMIF
- MAST Phase I mainly addressed **CTF** issues
 - **STPP** requires $\kappa \sim 3.2$, $\beta_N \sim 8.2$, $I_p/I_{rod} \sim 1$

| | STPP | CTF |
|---|------------------|-----------------|
| Aspect ratio, A | 1.4 | 1.6 |
| Major/minor radius, R_0/a (m) | 3.42/2.44 | 0.7/0.44 |
| Elongation, κ | 3.2 | 2.5 |
| Triangularity, δ | 0.55 | 0.4 |
| Plasma current, I_p (MA) | 31 | 8 |
| Centre rod current, I_{rod} (MA) | 30.2 | 12 |
| q_0, q_a | 2.9, 15 | 1.0, 6.0 |
| Greenwald number | 0.65 | 0.26 |
| $\beta_t \beta_N$ | 59, 8.2 | 15.3, 4 |
| Fusion Power | 3.1 GW | 26.1 MW |
| CD power (MW) | 50 | 45 |
| Auxiliary CD (MA) | 2.3 | 5.7 |
| Pressure driven current (MA) | 28.7 | 2.3 |
| Ohmic current (MA) | 0 | 0 |
| Confinement $H_{IPB98(y.2)}$ | 1.6 | 1.26 |

The Spherical Tokamak Power Plant

Design is strongly influenced by

- Desire for steady state operation
- Low toroidal field (high β), to keep design simple and minimise cost of electricity
- Neutron wall loading (determines device size)

Parameter Choice

Objective: to design a compact, steady state, $\sim 1\text{GW(e)}$ ST power plant (aspect ratio $A=1.4$)

Neutron wall loading (3.5MWm^{-2}) drives the size: $R=3.4\text{m}$

Cost of electricity limits toroidal field, $I_{\text{rod}} \approx I_p$

MHD limits $\beta_N=8.2$

High elongation required for $\sim 90\%$ pressure-driven current; vertical instability $\Rightarrow \kappa=3.2$

Required fusion power ($\sim 3\text{GW}$) $\Rightarrow I_{\text{rod}}=30.2\text{MA}$ ($\therefore I_p=31\text{MA}$)

Non-inductive current drive requires low density $\sim 1.1 \times 10^{20}\text{m}^{-3}$ ($\sim 60\%$ Greenwald)

Confinement, $\tau_E=1.6\tau_{\text{IPB98}(y,2)}$ or $1.4\tau_{\text{IPB98}(y,1)}$

Pressure driven current:

$$I_{bs} / I_{pl} = 28.7\text{MA} / 31\text{MA}$$

- With 90% bootstrap current, the current profile is hollow, but we maintain a monotonic q -profile

90% pressure driven current leads to non-monotonic current profile

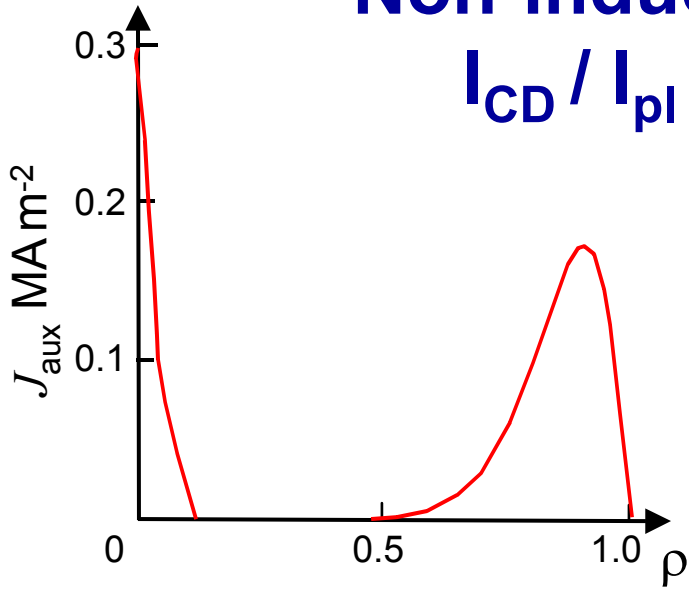

But in an ST we can maintain a monotonic q -profile

Note exclusion of low order rational surfaces

Non-inductive current drive:

$$I_{CD} / I_{pl} = 2.3\text{MA} / 31\text{MA}$$

Options for 2.2MA off-axis CD:
 40MW 80keV NBI, inclined beams
 20-30MW LHCD (3.7GHz), but antenna?

Options for 0.14MA on-axis CD:
 20MW 500keV NBI
 15MW ECCD (130GHz, 4th harm.)
 EBW very efficient, $\sim 0.1\text{AW}^{-1}$ but premature absorption unresolved

Parasitic absorption on outboard mid-plane an issue: included in ECCD calc, but not EBW

Neutral beam injection modelling

PF coil design and vertical stability

The desired plasma shape can be achieved with 3 pairs of PF coils

Vertical stability analysis indicates the equilibrium is close to marginal with no active feedback control

growth time = 10ms

stability index, $f_s = 3.5$

This can be achieved because of tight aspect ratio

low internal inductance (hollow J profile, $l_i(2) = 0.21$)

Prompt α -particle losses

Toroidal and poloidal fields are comparable on the outboard side
a full orbit code is required to calculate prompt
 α losses

The increase in B with R has a beneficial
'pinching' effect on the orbits
helps reduce prompt losses

Prompt losses, including TF ripple (<1%
across plasma), are tolerable ~4–5%

Transport Scenario

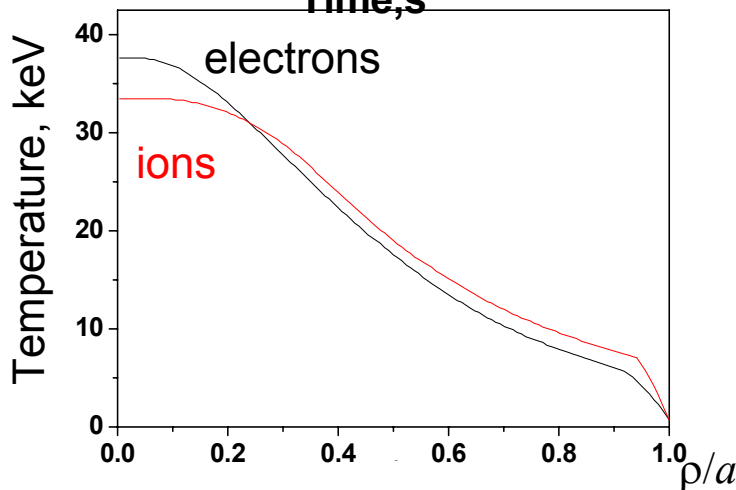

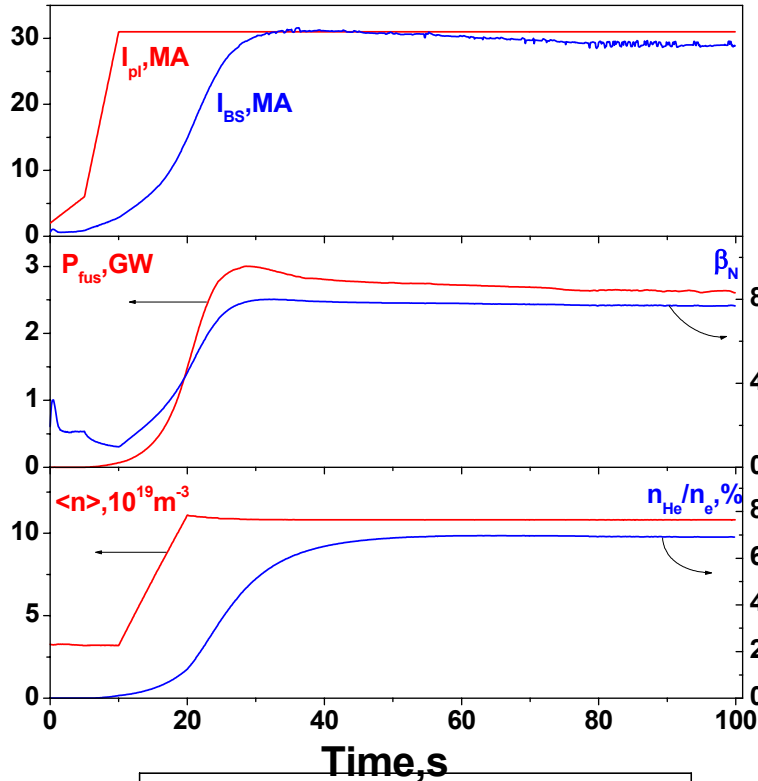

We specify density profile and total current, and calculate evolution of: current profile, He ash, temperature and fusion power

Thermal diffusivity has a constant part, adjusted so that $\tau_E = 1.4\tau_{IPB98(y,1)}$

Transport equations solved using ASTRA:

Employs 50MW NBI

Confirms 3GW fusion power
 90% pressure driven current
 comparable electron and ion temperature profiles

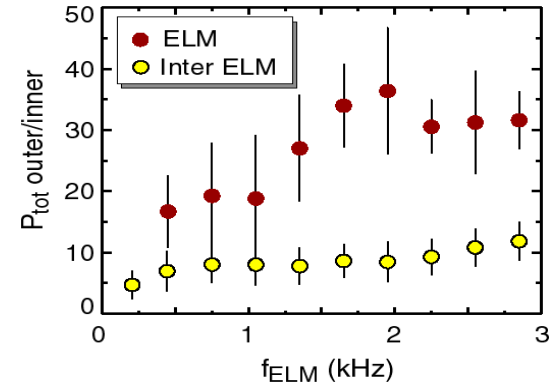

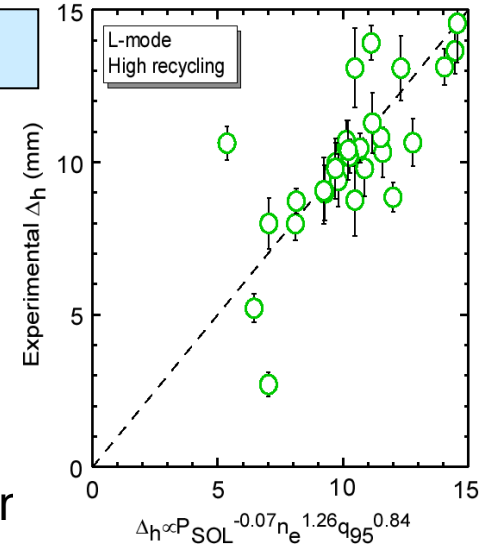

Exhaust

ST geometry \Rightarrow most heat goes to the outboard divertor leg (95% in MAST L-mode) \Rightarrow

Extrapolate from MAST?

SOL width

Power load linear with P_{SOL} (justification?)

Or take a scaling for the SOL width based on interchange mode turbulence:

~28mm (3.3mm) SOL width at outboard (inboard) divertor
 assume 50% radiated power

outboard loading: ~40MWm⁻² (10° angling of divertor plate)

inboard loading: ~26MWm⁻² (5° angling of divertor plate)

Engineering Design

Centre column:

650 tonnes, water-cooled
constructed from 30 tapered copper plates,
wrapped around a central tube
thin steel shield provides effective
protection

First wall and blanket:

martensitic steel first wall
lithium silicate breeding blanket, with Be
multiplier, separated by He-cooled steel
plates

T breeding ratio ~ 1.1

PF coils:

normal-conducting Cu divertor coil
super-conductor for other 2 pairs (normal
conducting Cu an option)

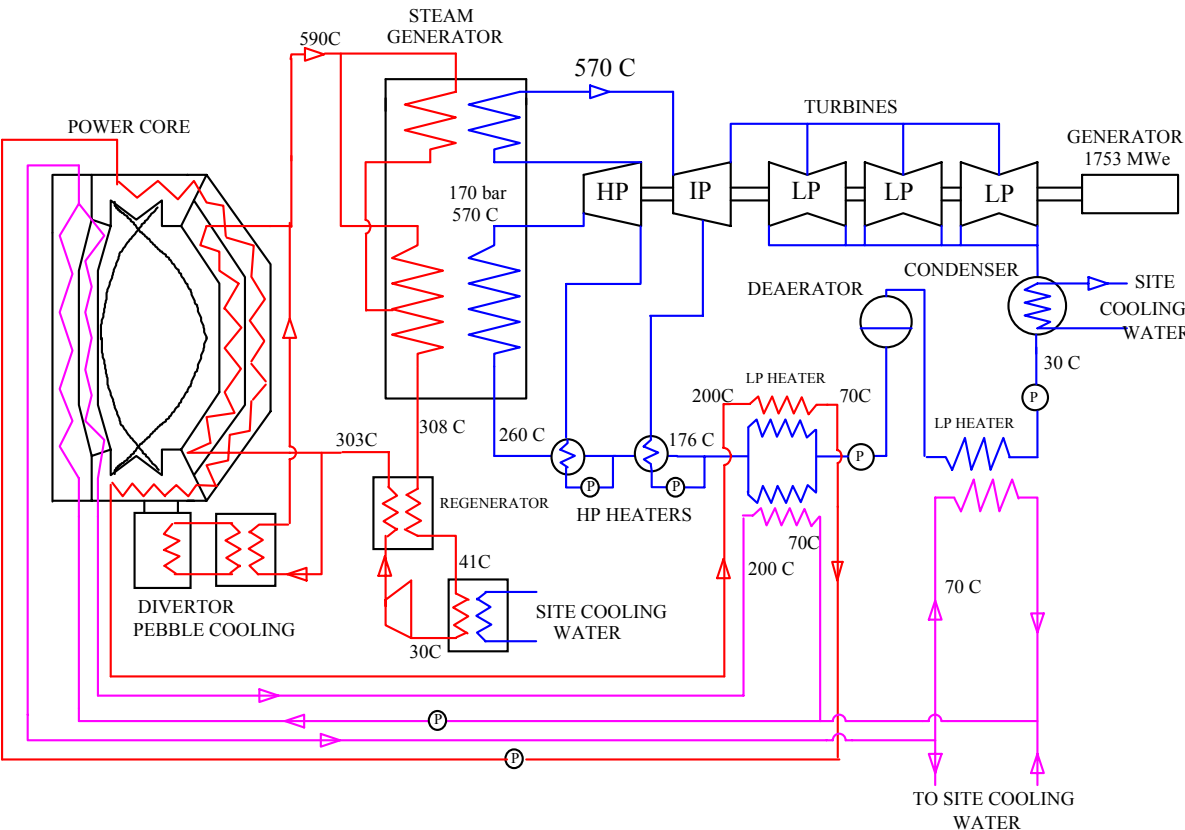

The power cycle

Design of power cycle takes account of wide spectrum of heat sources:

~80% at high T (~600°C)

~20% at low T (70-200°C)

Total fusion thermal input:

3.3GW

Gross electrical output:

1.75GW

30% of the output goes into driving the main electrical subsystems

The design has been kept simple to ease maintenance

Maintenance schedule:
 centre column replaced and
 refurbished every 2 yrs
 removal of centre column allows
 easy access to blanket modules
 mid-plane modules replaced
 every 2 yrs (others 4 yrs)

Components Test Facility (CTF)

Many in the fusion community feel that there is a need for CTF
IFMIF could test small material samples
CTF could test larger scale components, and would complement IFMIF data

The requirements of such a device are:

To provide sufficient neutron flux with limited T-consumption (no T breeding assumed)

Drives one to a compact device: the ST is suitable

Must operate in steady state (eg ~40% availability)

Ideally should be available on a nearer term time-scale than the power plant

Less aggressive physics assumptions

Components Test Facility design (example)

Test cassette
>6m² test area
at 1.4MWm⁻²

Copper centre
column

Induction coil
for plasma formation

Theoretical feasibility studies (physics and engineering) have shown that the ST has a role to play in the development of fusion power

Many of the issues are the same as those for ITER, but in addition it is important that MAST and other STs:

confirm the encouraging theoretical predictions:

high β operation

high elongation, high bootstrap current scenarios

good confinement

current drive efficiency (NBI and RF)

improve confidence in areas of uncertainty:

exhaust and ELMs

fast particle instabilities

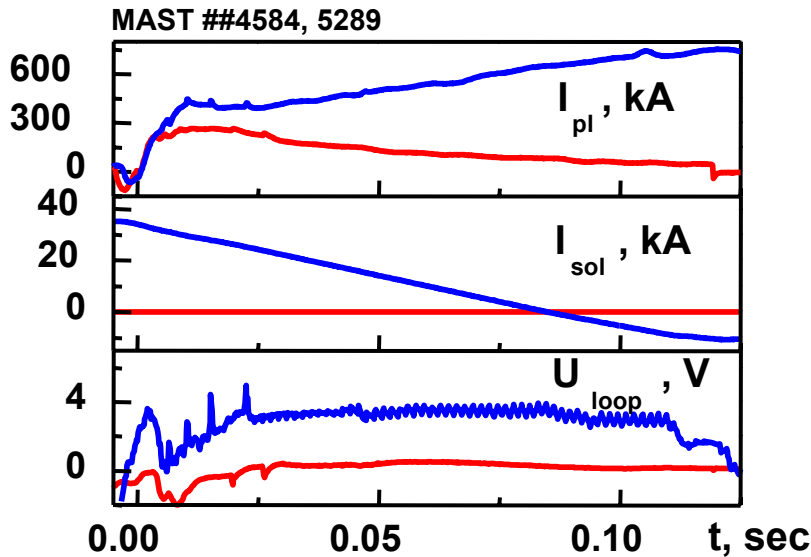

impact of sawteeth

neoclassical tearing modes and resistive wall modes

non-inductive start-up

Non-solenoid start-up and current ramp

Plasma formation without use of solenoid flux demonstrated

CURRENT RAMP at $U_{loop} \sim 0$

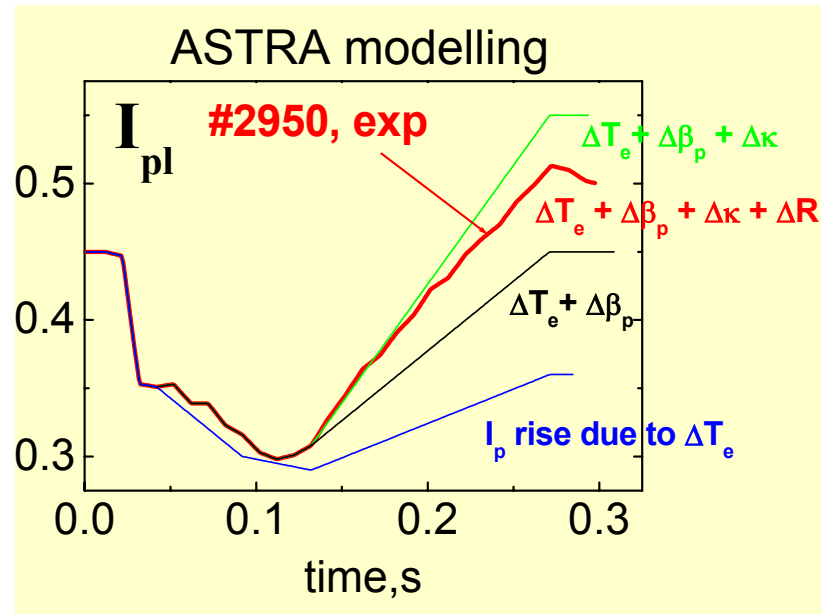

Plasma current can be ramped-up without use of the solenoid flux (ASTRA simulations)

Non-solenoid start-up and current ramp

Plasma current can be ramped-up using only flux from BV coils during NB heating and sustained for $\tau >$ resistive time

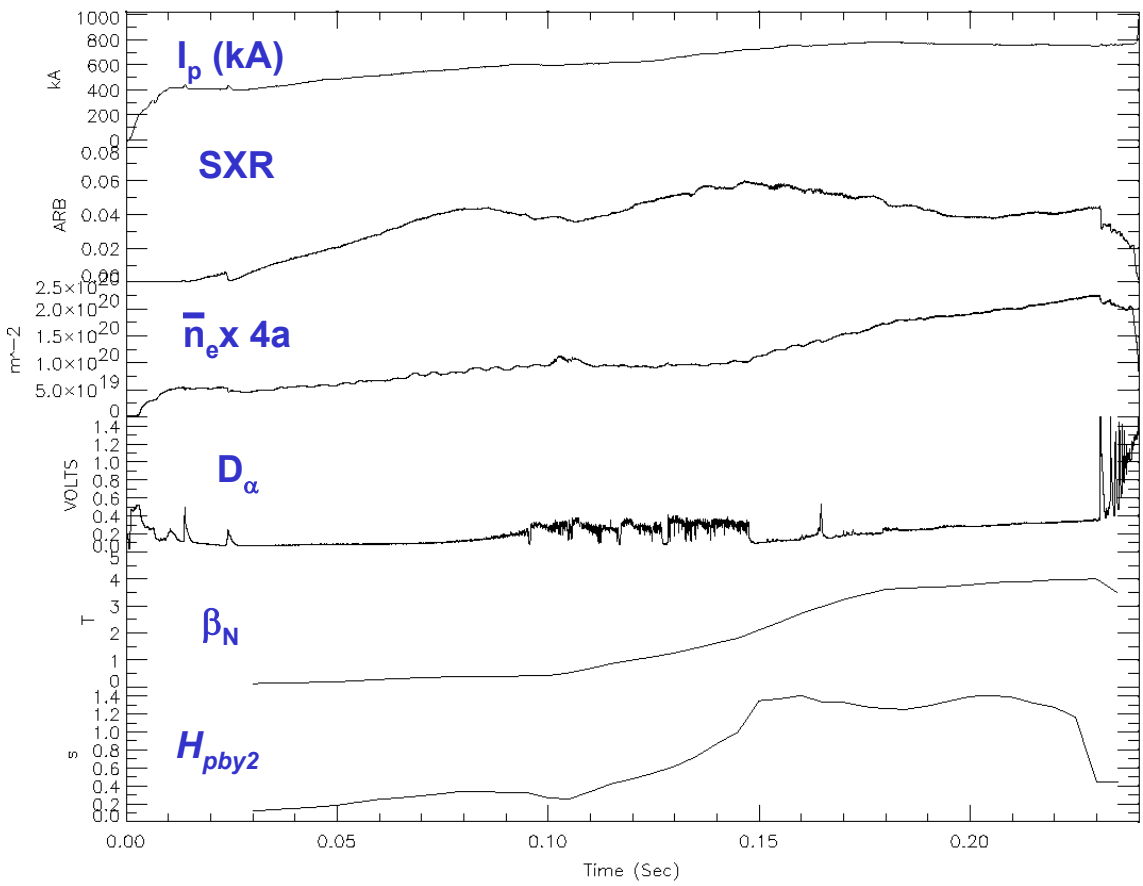

Plasma current doubled at constant U_{loop} during NBH
only 20% assigned to change in resistivity

Plasma current sustained at zero U_{loop} for 0.2s, which is \sim resistive time

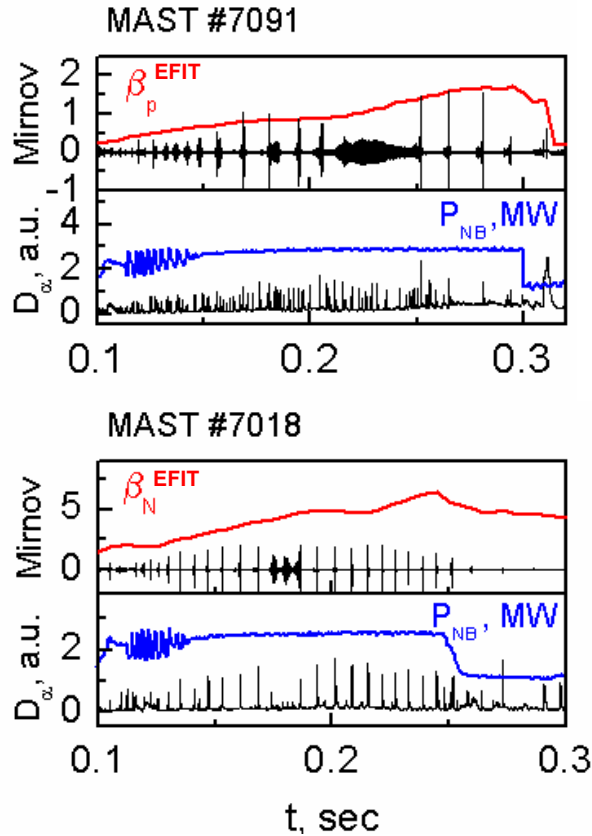

Contribution to the baseline ST scenario

MAST #6326, HH98y2 ~ 1.4, $\beta_N \sim 4$, $G \sim 0.6$

High-beta **ELM-free** H-mode with $q(0) > 1$

High beta discharges have low MHD activity:

MHD activity is low at high beta for broader (H-mode) profiles

High beta sustained for several confinement times:

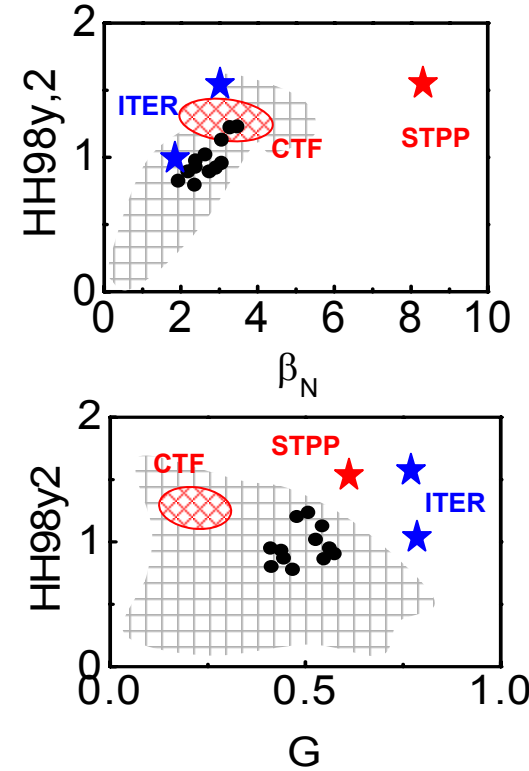

High-beta ELMy H-mode with $q(0) > 1$

Contribution to the baseline ST scenario

| CTF ops point | Achieved | simultaneous? |
|--------------------------------|-----------------------------|--------------------------------------|
| $A = 1.6$ | $A = 1.35 - 1.6$ | |
| $\kappa \sim 2.5$ | $\kappa \sim 2.45$ | not with A |
| $I_i \sim 0.54$ | $I_i \sim 0.5$ | not with β_N |
| $\beta_N \sim 4.0$ | $\beta_N > 5$ | not with I_i |
| $I_p/I_{rod} \sim 0.67$ | $I_p/I_{rod} \sim 0.84$ | |
| HHpby2 ~ 1.26 | HHpby2 > 1.5 | |
| $I_{non-ind}/I_p \sim 30\%$ | $I_{non-ind}/I_p \sim 50\%$ | not with A, κ , I_p/I_{rod} |
| $G = 0.27$ | $G > 1.5$ | |
| $\tau_{He}/\tau_E \sim 6 - 10$ | ? | check |

Many of parameters required for ST Component Test Facility have been achieved simultaneously

However, access to operating point of the ST Power Plant is a challenge for future experiments

MAST operating space with **future ST** and **ITER** parameters (dots - kinetically validated data with low FP component and $-0.05 \leq (dW/dt)/P \leq 0.35$)

H Wilson, M Valovic

Experiments needed to advance CTF operation point studies:

CTF outstanding issues:

- OPS at $I_p/I_{rod} \sim 0.7$ with high β_N and κ , low l_i and at $A = 1.6$
- Transport studies at high I_p/I_{rod} and high β (i.e. $I_p > 1\text{MA}$, $T_e > 1\text{keV}$)
- Particle transport, ash removal
- Confirm NBI CD, explore RF alternatives (eg EBW)

Other Next Step ST-relevant studies

- More high β studies, **limits**, low l_i
- Plasma control at high elongation
- B_V ramp studies and **overdrive** demonstration
- Non-solenoid **start-up** (including ECRH/**EBW** start-up) and integrated non-solenoid scenario

Conclusions

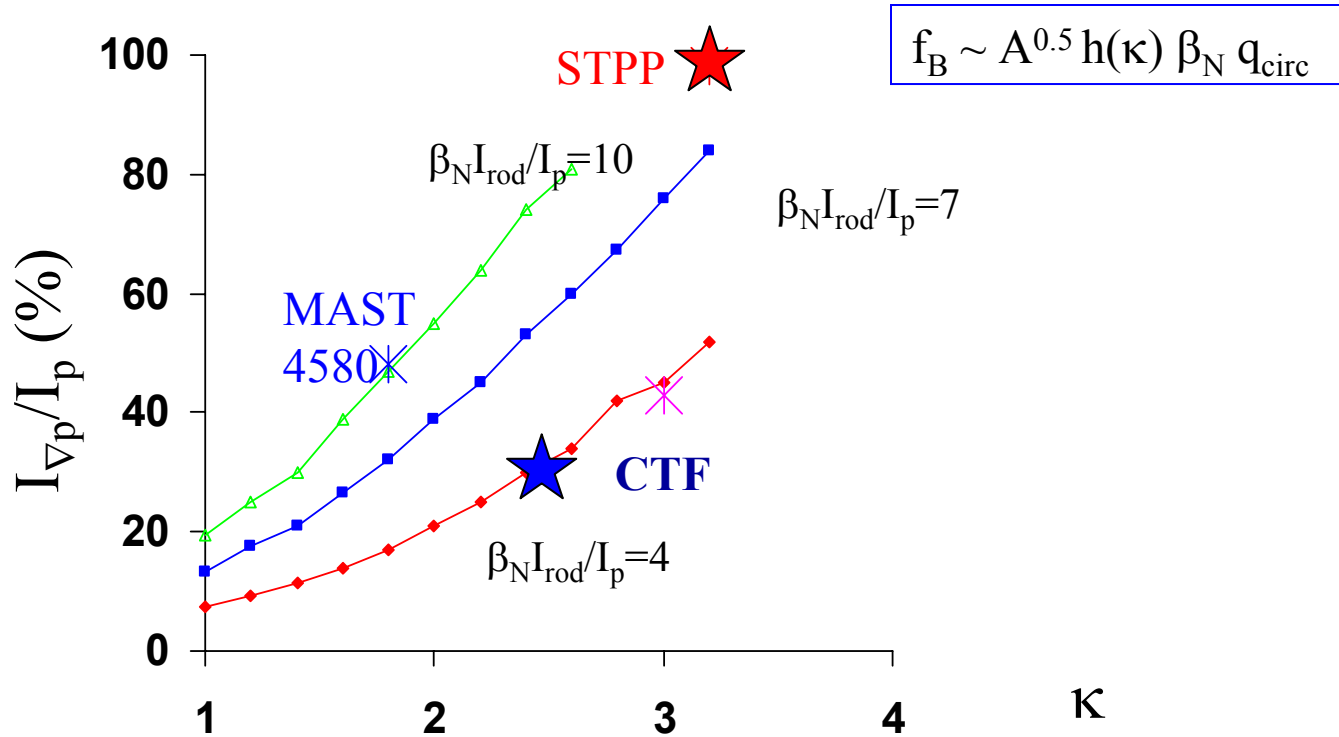

Theoretical feasibility studies (physics and engineering) have shown that the ST has a role to play in the development of fusion power

Considerable advances in areas relevant to the physics basis for operations in next-step STs (*start-up, current ramp, stability, confinement, current sustainment and exhaust issues*)

Together with the extensive array of high quality diagnostics on MAST, these results provide an excellent platform for further input to key physics studies and issues of specific relevance to the viability of the ST concept

High pressure-driven currents in STs

MAST #4580 has $A = 1.33$, $I_p = 0.675\text{MA}$, $I_{rod} = 1.87\text{MA}$, and $\beta_N = 4.5$

CTF has $A = 1.6$, $I_p = 8\text{MA}$, $I_{rod} = 12\text{MA}$, and $\beta_N = 4.0$

ST power plant has $A = 1.4$, $I_p = 31\text{MA}$, $I_{rod} = 30.2\text{MA}$, and $\beta_N = 8.2$
