#### **Motivation and observations**

- Fast ion confinement is an important element of a fusion device
  - Optimize the plasma heating and current drive
  - Avoid damage from localized particle losses to wall
- Recent focus on the combined effect of multiple fast particle modes

   Overlap of wave-particle resonances greatly enhances transport
- Direct coupling between modes experimentally documented
  - Non-linear coupling between Toroidal Alfvén Eigenmodes Podestà NF 2011
  - 3 wave coupling among TAE and Energetic Particle Modes Crocker PRL 2006
  - Simultaneous avalanches of Toroidal and Global AE Fredrickson NF 2012
- Fast ions represent a common element of many instabilities

#### **Fast-ions can modify MHD instabilities**

#### Instabilities can modify fast ion distribution

#### Fast-ions can mediate the interaction between instabilities

## The spherical tokamak is an excellent laboratory to study mode interplay

- High  $\beta$ , close to ideal stability limits
  - favors the appearance of ideal kinks, RWM, NTM
- Low  $B_{tor,}$  high density  $\rightarrow$  "low" Alfvén speed
  - large population of super alfvénic ions
  - favors the drive of Alfvén Eigenmodes (AE)

| NSTX parameters |        | Fast lons from NBI                              | NSTX diagnostics |  |
|-----------------|--------|---|------------------|--|
| Major radius    | 0.85 m | 3 sources, total P <sub>NBI</sub> ≤ 6 MW        | Plasma           | TS, CX, MSE                            |
| Aspect ratio    | ~2     | $E_{injection} \le 90 \text{ keV}$              | Fluctuations     | Mirnov ,SXR,                           |
| Plasma current  | ~1 MA  | 1 <v<sub>beam/V<sub>Alfven</sub> &lt; 5</v<sub> |                  | Reflectometry, BES                     |
| Toroidal field  | <0.6 T | Larmor radius <20 cm                            | Fast lons        | Neutrons, FIDA, NPAs,<br>Loss detector |

#### Multiple types of modes coexist at the start of current flat top

- H-mode,  $B_{tor}=0.35T$ ,  $I_p=900k$ -  $P_{NBI}=4-6$  MW,  $\beta_N \approx 2.5-3.5$
- Multiple types of concurrent MHD activity:
  - Reversed Shear AE
  - Toroidal AE (bursting)
  - Global/Compressional AE (bursting/continuous)
- Onset of Low Frequency MHD at t=220 ms (2<q<sub>min</sub><3)</li>
  - Rotation collapses (-15kHz)
  - $-\beta_N$  ramp stops
  - High frequency modes react

### High frequency modes appear after onset of LF mode

- Low Frequency mode enters with multiple toroidal harmonics
- n=1 (8kHz) and n=2 (16kHz) persist
- Initial chirp associated with the toroidal rotation drop (-15kHz)
- Cluster of Compressional AE in the 1.5-2.2 MHz range (~0.3  $\Omega_{ci}$ )
- Frequent observation in H-mode
- Driven by coupling with fast ions
- Reduced neutron rate indicates effect on fast ion confinement
  - -8% at mode onset
  - -13% in relaxed phase (TRANSP)

### Low frequency mode strongly affects fast-ion population

Hot Balmer  $D\alpha \rightarrow FIDA$  density:

$$n_{FIDA} = \frac{1}{n_0} \int_{\lambda_1}^{\lambda_2} s_{FIDA} d\lambda$$

- n<sub>FIDA</sub> provides local information about fast ion density n<sub>fast</sub>
- Affected by the velocity space response of the diagnostic
  - Depletion n<sub>FIDA</sub> <u>consistently</u>
     observed after mode onset:
    - up to 30% reduction
    - 10 ms time scale
    - outboard plasma affected first and more strongly

- What is the amount of fast ion losses and redistribution induced by the low frequency MHD?
- Can redistribution have a role in the destabilization of CAE?

- 1. Characterization of low frequency MHD
- 2. Computation of losses and redistribution caused by the low frequency MHD
- 3. Characterization of CAE and coupling with fast ions

- What is the amount of fast ion losses and redistribution induced by the low frequency MHD?
- Can redistribution have a role in the destabilization of CAE?

- 1. Characterization of low frequency MHD
- 2. Computation of losses and redistribution caused by the low frequency MHD
- 3. Characterization of CAE and coupling with fast ions

#### LF-MHD appears as perturbation near the plasma edge

- Tangential SXR camera (20 chords, R<sub>tan</sub> = 1.3-1.55 m, 50 μm Be)
- Evolution of line-integrated emissivity captures mode dynamics
- Periodic expansion-compression at 8 kHz for r/a>0.6

#### **Reflectometer provides local measurement of radial displacement**

- Multi channel reflectometer (16 channels, 30-75 GHz)
- Edge density peak  $\rightarrow$  Cut-off locations along plasma pedestal
- Amplitude of radial oscillation ±9 mm (at 8 kHz)

#### Free boundary PEST simulation predicts instability to n=1 kink

- Ideal MHD code PEST used to determine mode structure
- Configuration is *linearly* unstable to n=1 kink under these conditions:
  - Pedestal pressure gradient
  - Reversed shear in plasma core
- Solution is a global kink
  - Large amplitude at plasma periphery
  - Radial displacement indicates compression of outboard plasma edge

#### **Developed a synthetic diagnostic for Soft X-rays**

1. n<sub>e</sub> and T<sub>e</sub> perturbation from radial displacement:

$$\delta n_e = -n_e \nabla \cdot \xi_r - \nabla n_e \cdot \xi_r$$
$$\delta T_e = (1 - \gamma) T_e \nabla \cdot \xi_r - \nabla T_e \cdot \xi_r$$

2. SXR emissivity assuming carbon impurity only:

$$E_{SXR} = n_e^2 R_C(T_e) \to \delta E_{SXR}$$

- 3. Integration along view lines
- 4. Rigid toroidal rotation at mode frequency (8 kHz)

Assumption: structure to linear solution is preserved in the saturated phase

D NSTX-U

#### Kink structure validated against SXR measurements

- Linear solution does not provide saturated amplitude
- Normalize PEST radial displacement to reproduce ΔR<sub>edge</sub>=±9 mm excursion measured by reflectometer
- Reasonable agreement obtained with:
  - B<sub>z</sub> at Mirnov coil ≈ 15G
  - Profile of SXR fluctuation

- What is the amount of fast ion losses and redistribution induced by the low frequency MHD?
- Can redistribution have a role in the destabilization of CAE?

- 1. Characterization of low frequency MHD
- 2. Computation of losses and redistribution caused by the low frequency MHD
- 3. Characterization of CAE and coupling with fast ions

- What is the amount of fast ion losses and redistribution induced by the low frequency MHD?
- Can redistribution have a role in the destabilization of CAE?

- 1. Characterization of low frequency MHD
- 2. Computation of losses and redistribution caused by the low frequency MHD
- 3. Characterization of CAE and coupling with fast ions

## Full-orbit Monte-Carlo code SPIRAL predicts fast-ion redistribution and small particle losses

- Beam ions introduced at uniform rate along a 25 ms simulated time window using *birth profile from NUBEAM* code
- Fast ion orbits computed including collisional slowing-down and pitch angle scattering
- Energy slowing down time <20 ms for 90keV ion → final state represents the *stationary distribution*
- Computation performed *with* and *without* kink at t=0.25 s (relaxed state)

- Small increase of fast-ion losses (-3% confined particle )
- 8% decrease in neutron production rate

#### Confined fast-ions are redistributed by the kink in real space (R,Z)

54th APS-DPP – Interplay between MHD instabilities, A. Bortolon (10/29/2012)

### Kink effect on radial profile of fast-ion density

- Decrease of n<sub>fast</sub> by ~20% in the core
- Increase of n<sub>fast</sub> for R<0.9m (inboard) and R>1.3m (outboard)
- Accounting for the FIDA weight function (λ=653nm, R=1.2m) leads to an apparent collapse of -25% in the core

#### Confined fast-ions are redistributed by the kink in velocity space (energy, pitch)

#### Confined fast-ions are redistributed by the kink in velocity space (energy, pitch)

Differential distribution function:  $\Delta F(E,p) = F_{kink} - F_{nokink}$ Integrated over plasma volume F(E,p) without kink  $\Delta F(E,p)$ F(E,p) with kink 200 200 60 180 180 40 160 160 0.5 0.5 0.5 140 140 20 Pitch  $(v_{\parallel}^{\prime}v)$ 120 120 0 0 0 0 100 100 80 80 -20 60 60 -0.5 -0.5 -0.5-40 40 40 20 20 W<sub>FIDA</sub>>0.5 -60 -120 40 60 80 20 40 60 80 20 80 60 40 Energy [keV] Energy [keV] Energy [keV] Slowing down Slowing down distribution distribution In presence of the kink: shifts towards  $V_{||}/V = 1$ Strong anisotropy

- What is the amount of fast ion losses and redistribution induced by the low frequency MHD?
- Can redistribution have a role in the destabilization of CAE?

- 1. Characterization of low frequency MHD
- 2. Computation of losses and redistribution caused by the low frequency MHD
- 3. Characterization of CAE and coupling with fast ions

- What is the amount of fast ion losses and redistribution induced by the low frequency MHD?
- Can redistribution have a role in the destabilization of CAE?

- 1. Characterization of low frequency MHD
- 2. Computation of losses and redistribution caused by the low frequency MHD

3. Characterization of CAE and coupling with fast ions

#### **Mirnov array measurements show multiple sequences**

- Clusters of modes with 0.3< $\omega/\Omega_{ic}$ <1 identified as CAE
- Toroidal mode numbers n=9-13,  $ilde{B}_{\parallel} > ilde{B}_{\perp}$
- Propagating in direction of neutral beam injection

2 sequences of modes ascending *frequencies* and *n* are present

#### CAE are expected to be localized in the outboard region

• CAE wave equation for electric field

$$(\nabla_{R,Z}^2 - V) E_Z = 0 \quad V(R,Z) = k_{\varphi}^2 - \frac{\omega^2}{v_A^2}$$

Wave in a box form (Schroedinger-like) Effective Potential Well (equilibrium and toroidal structure)

- Solutions will be standing waves localized within the potential well V(R,Z,ω)
- Eigenmodes can be classified according to effective quantum numbers:

$$\vec{k} = \left(rac{n}{R}, \, rac{2\pi m}{L_Z}, \, rac{2\pi s}{L_R}
ight)$$

• n, m, s number of wavelengths in toroidal, vertical, radial direction

## Eigenvalue equation solved numerically in realistic 2D equilibrium

54<sup>th</sup> APS-DPP – Interplay between MHD instabilities, A. Bortolon (10/29/2012)

#### Fast-ion redistribution by kink populates CAE resonances

• Fast ions couple with CAEs through Doppler shifted ion cyclotron resonance

$$\omega = k_{\parallel}^{nms} v_{i,\parallel} + l \,\Omega_{ci}, \quad l = -1, 0$$

- Knowledge of the mode structure (n,m,s) allows to identify fast ions that resonate with the wave
- Determine resonance curves for the observed modes (in velocity space)
- Self-consistent MHD simulations (HYM) of co-propagating CAE in progress to determine fast ion drive
   Belova PP8.00022 Wednesday PM

#### Conclusions

- Fast ions can mediate the interaction between instabilities that differ by localization, timescales and underlying physics
  - Complex integrated analysis is required to investigate these processes experimentally
- In NSTX H-modes, kHz-frequency ideal kinks can induce substantial fast ion redistribution in real and velocity space
  - Redistribution to resonant phase space regions could explain the destabilization of CAEs observed in presence of kinks
- In simulations, fast ion redistribution with small losses obtained in presence of low-f peripheral fields
  - Conceivable to use of 3D perturbations to affect stability of AE

#### **Resonance conditions for co-propagating CAE**

- CAE are driven by bump-on-tail fast ion distribution function
- Excited through Doppler shifted ion cyclotron resonance
