Multiple radial heat flux profiles are averaged for data analysis

- 2-D surface temperature data from IR camera are used for heat flux calc.
- Heat flux data in (x, y) plane is re-mapped to the (r, Φ) plane and all radial heat flux profiles are combined to create an average profile

$$\bar{q}_{peak,tor} = \sum (q_{peak,rad}) / N_{rad}$$

$$\bar{\lambda}_{q,tor} = \sum (\lambda_{q,rad}) / N_{rad}$$

Peak heat flux and heat flux width are determined by total power and wetted area

- Total deposited power to divertor:

$$P_{div, IR} = \int 2\pi r \bar{q}_{tor}(r) dr$$

- Wetted area

$$A_{wet} = P_{div, IR} / \bar{q}_{peak, tor}$$

- Integral heat flux width

$$\begin{aligned} \bar{\lambda}_{q, tor}^{int} &= P_{div, IR} / 2\pi r_{peak} \bar{q}_{peak, tor} \\ &= A_{wet} / 2\pi r_{peak} \end{aligned}$$

- Total deposited energy to divertor

$$W_{div, IR} = \int P_{div, IR} dt$$

Temporal evolution and dependence on the ELM size of $P_{div, IR}$ and A_{wet}

Characteristics of several ELM types in NSTX

- Type-I ELMs:
 - Large ELM size, good confinement, high heating power
- Type-III ELMs:
 - Medium size, poorer confinement, lower heating power
- Type-V ELMs:
 - A small ELM regime in NSTX, good confinement, $n = 1 - 2$, indiscernible individual D_α peaks, IR and GPI data

R. Maingi, NF 2005

Wetted area decreases for type-I and III, and increases for type-V during the ELM

Type-I ELMs

- Wetted area (A_{wet}) and heat flux width (λ_q) **decrease** during the ELM
 - Significant A_{wet} reduction, 20 - 50%
 - Inverse relation between λ_q and q_{peak}
 - Same trend for type-III ELMs
 - Contrary to results from other tokamaks

Wetted area decreases for type-I and III, and increases for type-V during the ELM

Type-I ELMs

Type-V ELMs

- Wetted area (A_{wet}) and heat flux width (λ_q) **decrease** during the ELM
 - Significant A_{wet} reduction, 20 - 50%
 - Inverse relation between λ_q and q_{peak}
 - Same trend for type-III ELMs
 - Contrary to results from other tokamaks
- Clear **increase** of A_{wet} and λ_q during ELM
 - Contrary to type-I and type-III ELMs
 - Only modest q_{peak} rise (~20 - 30%) due to A_{wet} increase

Dependence of A_{wet} on ELM size shows unfavorable trend for type-I and III ELMs and favorable trend for type-V

- Type-I and type-III ELMs show similar trend:
 - A_{wet} (therefore λ_q) decreases during the ELM
 - The size of decrease becomes bigger with the size of ELM power $\rightarrow$ λ_q decrease worse for larger ELMs
- Type-V ELMs:
 - Shows favorable trend of A_{wet} (λ_q) increase and the size of increase is proportional to the ELM size
- Larger ELM size gives bigger impact on expansion and contraction of A_{wet}

A_{wet} decrease leads to q_{peak} increase with increasing ELM energy loss for **type-I ELMs** in NSTX

NSTX, type-I

JET, type-I

- NSTX: A_{wet} decreases with ELM energy loss $\rightarrow q_{\text{peak}}$ increases
- JET [1]: A_{wet} increases with ELM energy loss $\rightarrow q_{\text{peak}}$ constant
- Both machines show $A_{\text{wet}} \downarrow$ and $q_{\text{peak}} \uparrow$ for inter-ELM profiles

[1] T. Eich, PFMC 2013

Conclusions

- Wetted area (A_{wet}) determines heat flux width (λ_q) $\rightarrow$ decreases during type-I and III ELMs and increases during type-V ELMs
- The size of A_{wet} change is proportional to the size of ELM for both increase and decrease cases
- Contrary to data from conventional tokamaks, eg JET and AUG, A_{wet} decrease leads to q_{peak} increase with increase of ELM energy loss in NSTX $\rightarrow$ ELM heat flux mitigation technique necessary (eg, Snowflake divertor, ELM control by 3-D fields, etc. for NSTX-U)

Future work:

- Relation of A_{wet} to pedestal pressure in wider parameter range
- Understanding of the transport processes for A_{wet} contraction

Back-up Slides

Type-III ELMs: Similar behavior to type-I ELMs

132403, type-III ELMs with high W_{tot} , $P_{\text{NBI}}=3.5\text{MW}$

- Similar behaviors to type-I ELMs are observed
 - $A_{\text{wet}} \downarrow$ and $\lambda_q \downarrow$ during ELM rise
 - Inverse relation between λ_q and q_{peak} at ELM

3-D field triggered ELMs: similar to type-I ELMs

- ELMs are triggered by applied 3-D fields, e.g. $n=3$ [1]

[1] J.M Canik, PRL **104** (2010), 045001

3-D field triggered ELMs: similar to type-I ELMs

- ELMs are triggered by applied 3-D fields, e.g. $n=3$ [1]
- Again, ELMs reduce A_{wet} and therefore $\lambda_{q,\text{tor}}$, similar to type-I ELMs

[1] J.M Canik, PRL **104** (2010), 045001

Toroidal asymmetry of peak heat flux and heat flux width is quantified

- Toroidal asymmetry (ε_{DA}) of peak heat flux (q_{peak}) and heat flux width (λ_q) is defined:

$$\varepsilon_{DA}(q_{peak}) = \sigma_{q_{peak}} / \bar{q}_{peak,tor}$$

$$\varepsilon_{DA}(\lambda_q) = \sigma_{\lambda_q} / \bar{\lambda}_{q,tor}$$

- σ_{peak} and σ_{λ_q} are the standard deviation of q_{peak} and λ_q over the data in the toroidal direction
- σ_{peak} and σ_{λ_q} are normalized to the toroidal mean values of q_{peak} and λ_q

J-W. Ahn, JNM **438** (2013), S317

Toroidal asymmetry of peak heat flux and λ_q increases during ELM for all ELM types

- Asymmetry of both q_{peak} and λ_q increases during ELM for all ELM types
- Generally appears to be proportional to peak heat flux
- $\epsilon_{DA}(q_{peak})$ is larger than $\epsilon_{DA}(\lambda_q)$ except type-V ELMs, $\epsilon_{DA}(q_{peak}) \sim \epsilon_{DA}(\lambda_q)$

Heat flux asymmetry for triggered ELMs follows similar trend to natural type-I ELMs

- Toroidal asymmetry immediately increases with 3-D field application
- Data for triggered ELMs at ELM peak times well aligned with those for naturally occurring type-I ELMs
