# Divertor heat flux reduction and detachment in CTF-relevant (highly shaped) plasmas

**V. A. Soukhanovskii  
and the NSTX Team**

**NSTX Team Review  
8 February 2007  
Princeton, NJ**

# NSTX FY08 milestone, ST development path and divertor physics studies motivate the XP

- NSTX Edge Physics Milestone FY2008  
“Study variation and control of SOL heat flux...”
- NSTX high  $\kappa$ ,  $\delta$  LSN plasmas (developed in J. Menard's XP) show potential for future ST-CTF:
  - high  $\beta_t$ ,  $\beta_n$
  - long pulse, high H89P scaling factor
  - high bootstrap and non-inductive current fractions
  - small or no ELMs
- Test radiative and dissipative divertor techniques for divertor peak heat flux reduction in highly shaped plasmas
- Study lower divertor geometry effects on particle and heat fluxes
- Study upper divertor properties on particle and heat fluxes (new FY07)

# Divertor peak heat flux reduced by 2-5 with radiative/dissipative divertor in lower $\kappa, \delta$ plasmas

- Completed low  $\delta, \kappa$  part in 2006
- Multi-institutional experiment - LLNL, ORNL, PPPL, U Washington, UCSD
- C. J. Lasnier (LLNL staff at DIII-D) participated in 2005 experiment
  
- NSTX results to date (4 MW NBI lower  $\delta, \kappa$  H-mode plasma)
  - ☑ OSP does not detach at high densities ( $n_e \sim n_G$ ) as a result of short L and open divertor geometry. ISP detaches at low  $n_e, P_{in}$
  - ☑ Midplane neon puffing produces radiative mantle
  - ☑ Obtained OSP partial detachment with high-rate  $D_2$  puffing in ISP region
    - ✓ Peak OSP heat flux reduced by 2-5
    - ✓ Core confinement degrades within 2-5  $\tau_E$
    - ✓ H-L transition within 20-50 ms (too much gas)
    - ✓ X-point MARFE forms quickly
  - ☑ Obtained radiative divertor with moderate  $D_2$  puffing in PFR or ISP region
    - ✓ Peak OSP heat flux reduced by 2-5
    - ✓ Good core confinement (1.6 H89P), H-mode
    - ✓ Outer SOL in high recycling regime
    - ✓ X-point MARFE eventually forms as well
    - ✓ Promising scenario for future experiment

# Publications and collaborations

- Publications
  - Oral talk in NSTX session at APS 2005
  - PSI-17 poster
  - Two JNM papers (2005, 2007)
  - IAEA FEC 2006 individual poster and paper
  - Paper to be submitted to NF (01/2007)
  
- Collaboration potential
  - Discussed possible collaboration with DIII-D (through LLNL program)
  - Discussed collaboration with J. Myra (Lodestar)
  - Possible collaboration with MAST

# More favorable scaling of peak OSP heat flux with input power is obtained in higher $\kappa$ , $\delta$ plasmas

- Scaling depends on fueling location and gas injection rate
- $P_{SOL}$  is determined from measured and TRANSP-calculated quantities as

$$P_{SOL} = P_{NBI} + P_{OH} - dW_{MHD}/dt - P_{rad}^{core} - P_{fast\ ion}^{loss}$$

# Divertor heat flux reduction scenario in highly shaped plasmas may be different

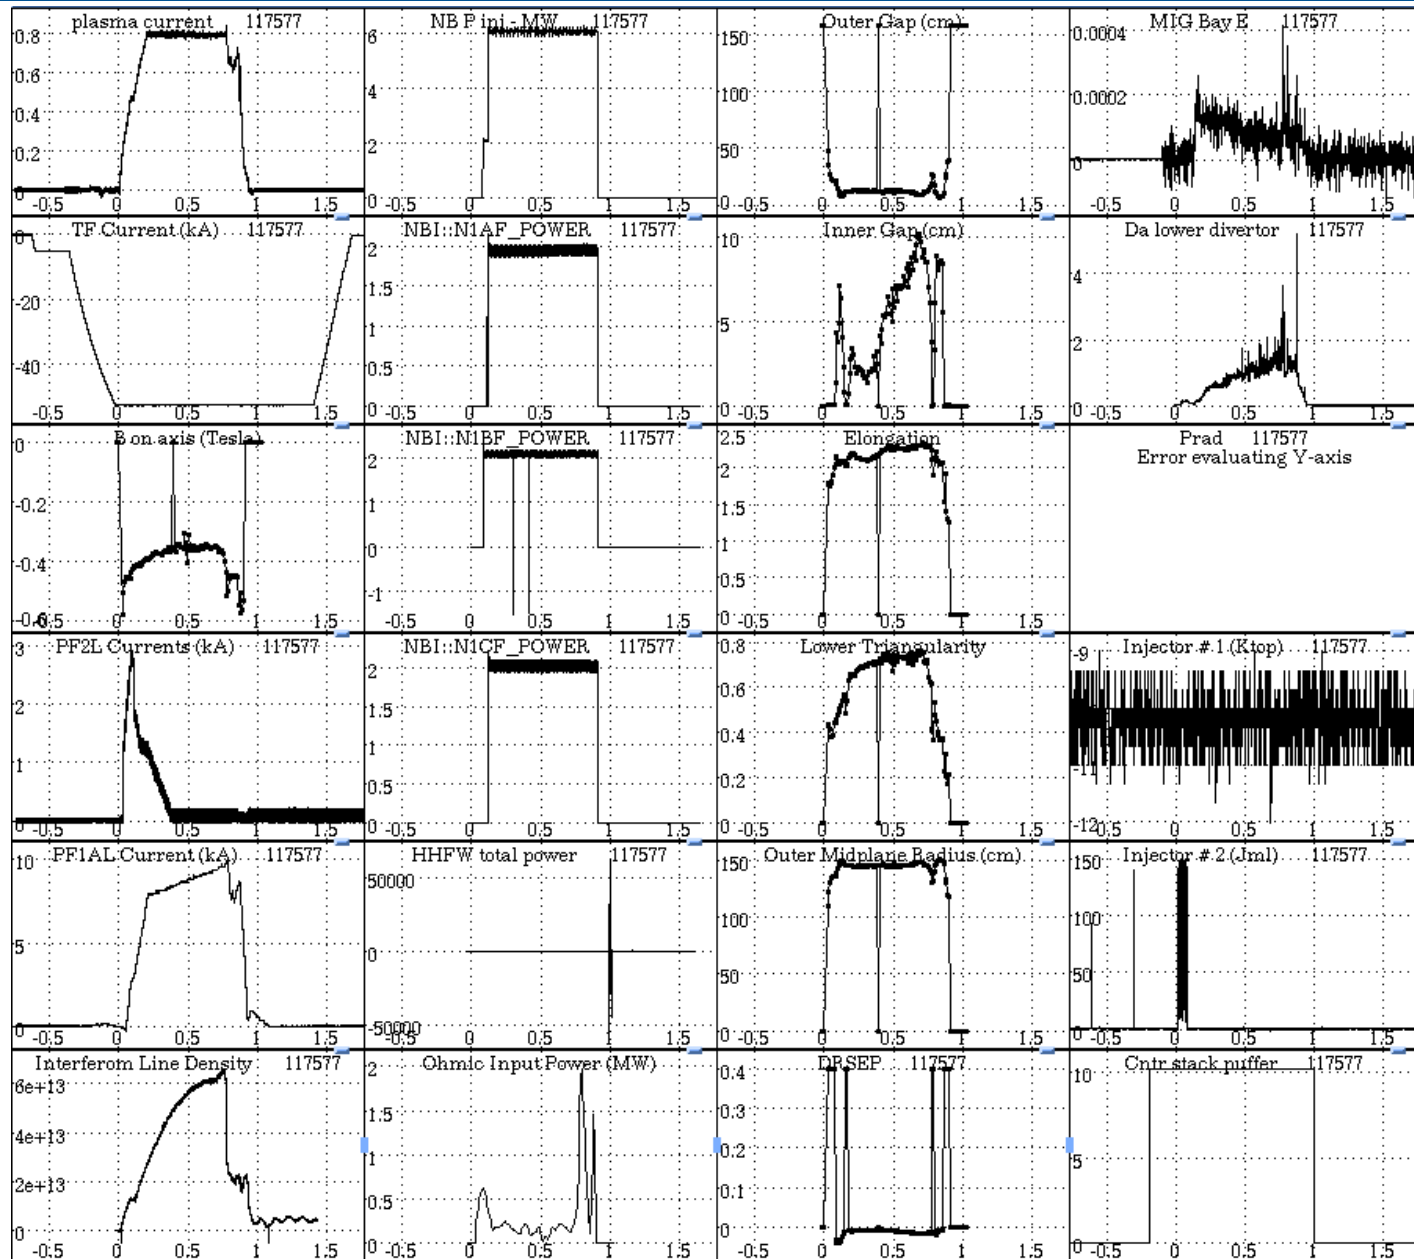

- High-performance long-pulse LSN H-mode plasmas (J. Menard)
- Poloidal flux expansion at OSP 20-25
- ISP on vertical target (detached), OSP on horizontal target
- OSP detachment threshold to be investigated (geometry)
- Divertor gas injectors in PFR and OSP region

# Run plan - overview

- **Divertor D<sub>2</sub> puffing (~ 0.5-0.7 day)**
  - Target plasma - 4-6 MW H-mode LSN plasma, 0.7-0.8 MA, 5 - 5.5 kG,  $\delta \sim 0.7-0.8$ ,  $\kappa \sim 2.3$
  - Try 200-400 Torr I / s from LDGIS and 100-160 Torr I /s from Branch 5 injectors
  - Diagnostic set is ready
- **Extrinsic impurity puffing (CD<sub>4</sub> or N<sub>2</sub>) (~ 0.2-0.5 day)**
- **Measure divertor heat flux profiles, D <sub>$\alpha$</sub> , D <sub>$\gamma$</sub> , C III divertor and midplane profiles, rad. power, particle fluxes, edge and divertor T<sub>e</sub>, n<sub>e</sub> for comparison with models**
- **If GPI diagnostic and fast cameras are available, test blob radial transport theory**
  - Proposed at NSTX RF FY 07 by J. Myra (Lodestar), also discussed by R. Maqueda (Nova Photonics), J. Boedo (UCSD)
  - Blob rad. velocity increases with resistivity (disconnection from sheath)
  - Disconnection is achieved through X-point cooling or OSP detachment
  - Use UCSD probe, GPI and fast cameras during divertor gas injections

# Shot template has been well developed

# Back-up slides

# UEDGE modeling guided detachment experiments

- Model divertor conditions vs  $P_{in}$ ,  $n_{edge}$  with UEDGE to guide experiment
- Generic low  $\kappa, \delta$  LSN equilibrium used
- Diffusive transport model
- Impurities (carbon) included
- Outer midplane  $n_e, T_e$  profiles matched,  $D_\alpha$  and IRTV not matched

 G. Porter, N. Wolf

Parallel momentum and power balance:

$$\frac{d}{ds} (m_i n v^2 + p_i + p_e) = -m_i (v_i - v_n) S_{i-n} + m_i v S_R$$

$$\frac{d}{ds} \left( (-\kappa T_e^{5/2} \frac{dT_e}{ds}) + n v_{||} \left( \frac{5}{2} (T_i + T_e) + \frac{1}{2} m_i v_{||}^2 + I_0 \right) \right) = S_E$$

# Large momentum and power losses are needed for divertor detachment according to 2PM-L

- Two point model with losses
- $f_p, f_m$  scanned,  $f_{cond}=0.9$
- $n_u, q_{||}, L_c$  from experiment

$$(1 - f_{power}) q_{||} = q_t = \gamma T_t n_t c S t$$

$$2 n_t T_t = f_{mom} n_u T_u$$

$$T_u^{7/2} = T_t^{7/2} + \frac{7}{2} \frac{f_{cond} q_{||} L_c}{\kappa_0 e}$$

$$\Gamma_t \sim \frac{f_{mom}^2 f_{cond}^{4/7}}{1 - f_{power}}$$

$$L_c = 20 \text{ m}, q_{||} = 25\text{-}30 \text{ MW/m}^2$$

# Why is it difficult to obtain OSP detachment?

- Connection length decreases to very short values within radial distance of 1-3 cm (both midplane to plate and X-point to plate)
- SOL temperature 10-40 eV (rather low)
- Weak  $dT_e/ds_{||}$  in high-recycling outer SOL
- Carbon cooling rate max at  $T_e < 10$  eV
- Recombination time:  
 $\tau_{rec} = 1./(n_e R_{rec}) \sim 1-10$  ms at  $T_e = 1.3$  eV
- Ion divertor residence time:  
 $\tau_{ion} = L_d/v_{ion} \sim 0.8$  ms (with  $v_{ion} \sim 10^4$  m/s)
- Open divertor geometry - high detachment threshold is expected
- Neutral compression ratio is 5-10 (low)

# Observed midplane and PFR pressure trends are due to open divertor geometry

- In reference discharges,  $n_U$  independent of  $P_{mp}$ , but a strong linear function of  $P_{PFR}$
- X-point MARFE critical PFR pressure is 0.5-0.6 mTorr
- Reference discharges never reach PFR critical pressure
- PDD discharges reach MARFE onset PFR pressure faster than RD discharges
- $P_{mp}$  similar in ref. and RD discharges
- $P_{mp}$  higher in PDD discharges (stronger gas puffing)
