Electromagnetic MGI Valves to Support NSTX-U Disruption Mitigations Studies Build & Tested

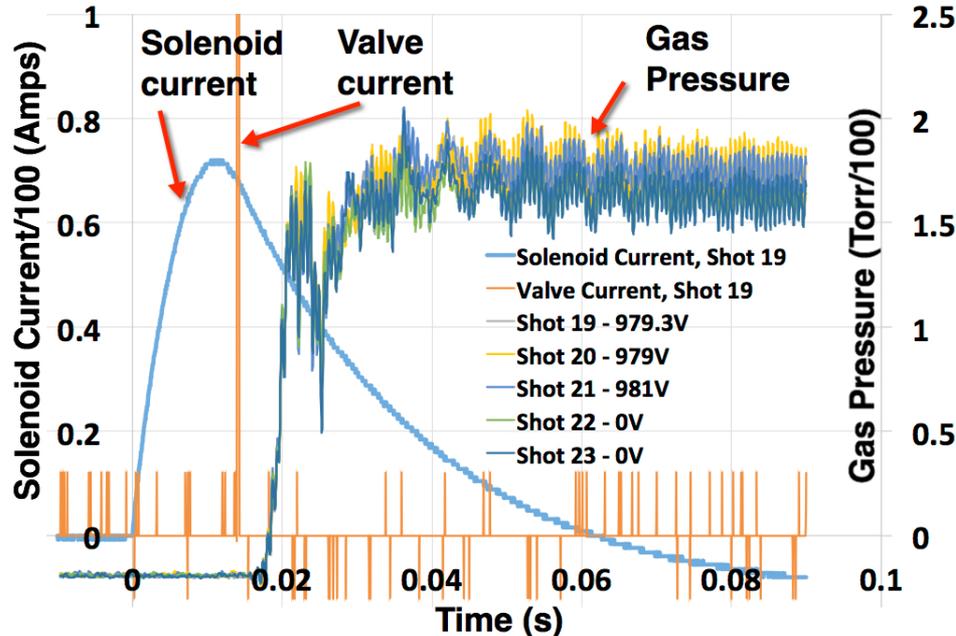

Solenoid driven using a 10 mF, 1kV Capacitor bank

Field between the two coils is 1.8T at 2kA coil current

V2- NSTX-U MGI Valve

V2 valve has two solenoids, with currents driven in opposite direction (based on ORNL ITER MGI Test Valve design)

FY15 NSTX-U MGI experiments will use three MGI valves at different poloidal locations

- This XP Plan

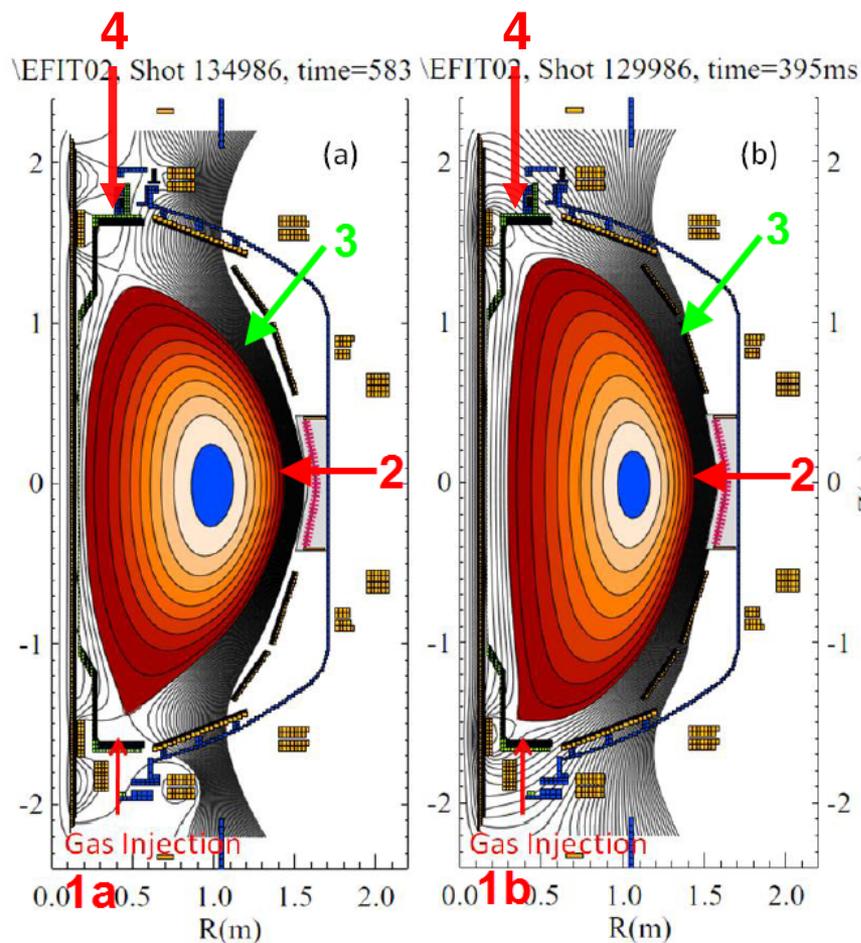

- Operate valves at ~ 5000 Torr (200 Torr.L Neon) [Increase to 10,000 Torr if NSTX-U limits can be increased]
- Compare mid-plane and PFR locations for gas assimilations studies using identical gas injection set-up
- Measure radiated power profiles, divertor heat loads and currents in divertor tiles, and compare to unmitigated discharges
- Use DN or LSN & USN discharges at low and high triangularity
- Run Time: 2 days

1a: Private flux region **1b:** lower SOL

2: Conventional mid-plane injection

3: Variation in poloidal location

4: Injection from the upper divertor region

Low triangularity

High triangularity
