Science

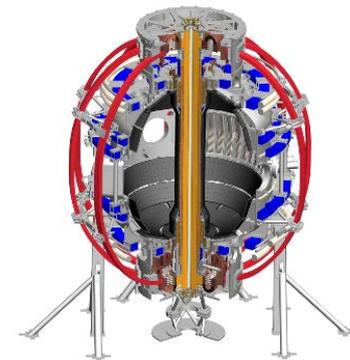

Progress and plans for NSTX Upgrade and prospects for next-step spherical tori

Jonathan Menard (PPPL)
NSTX-U Program Director

On behalf of the NSTX-U Research Team

American Nuclear Society - Student Branch
Department of Nuclear Engineering
University of California Berkeley
November 7, 2016

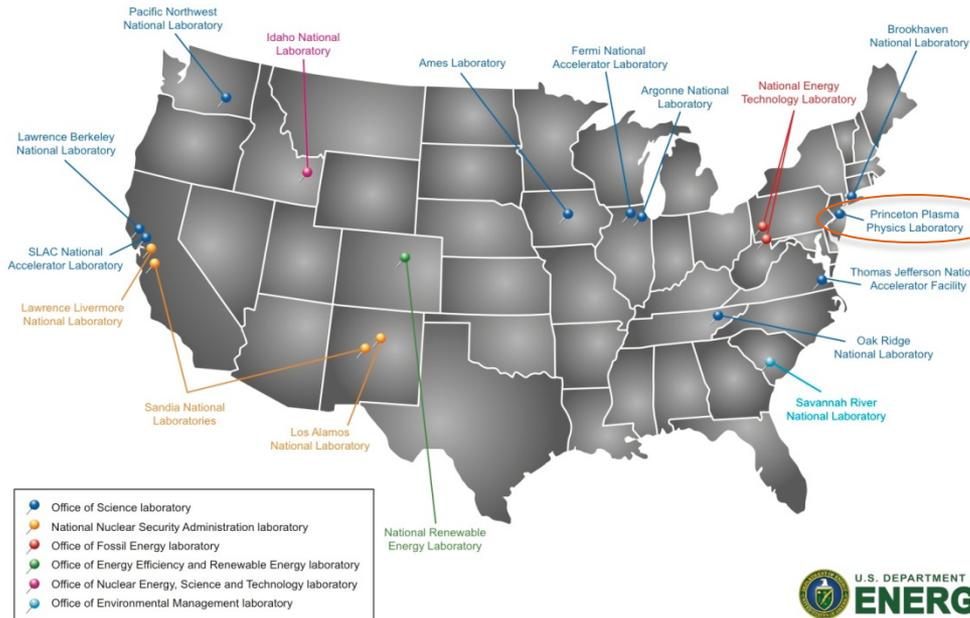

Outline

- Overview of PPPL, fusion, and plasma
- Plasma confinement issues
- What are tokamaks, stellarators, ITER?
- Motivation for studying spherical tokamaks
- NSTX Upgrade construction
- NSTX Upgrade scientific goals and questions
- Student and Faculty Opportunities at PPPL

PPPL: Princeton Plasma Physics Lab

- PPPL is one of 17 DoE national laboratories.
- We are managed by Princeton University but have a government mandate that focuses on fusion energy research and basic plasma science.

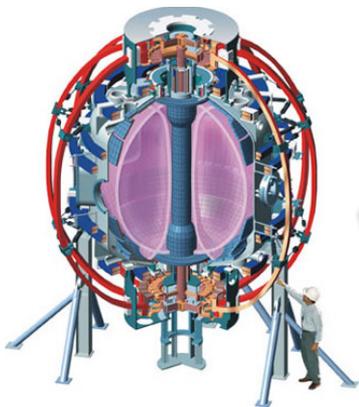

Department of Energy National Laboratories

- ~550 employees
- \$90-100M / year

At PPPL, we try to understand the many aspects of plasma physics

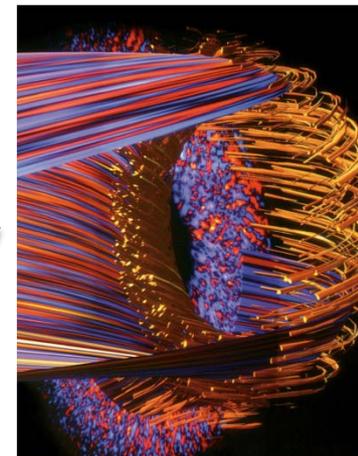

Fusion Research

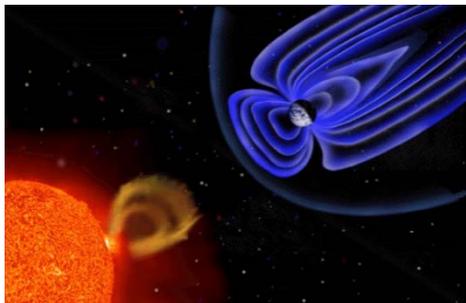

Basic plasma physics

Plasma theory and simulation

Astrophysical plasmas

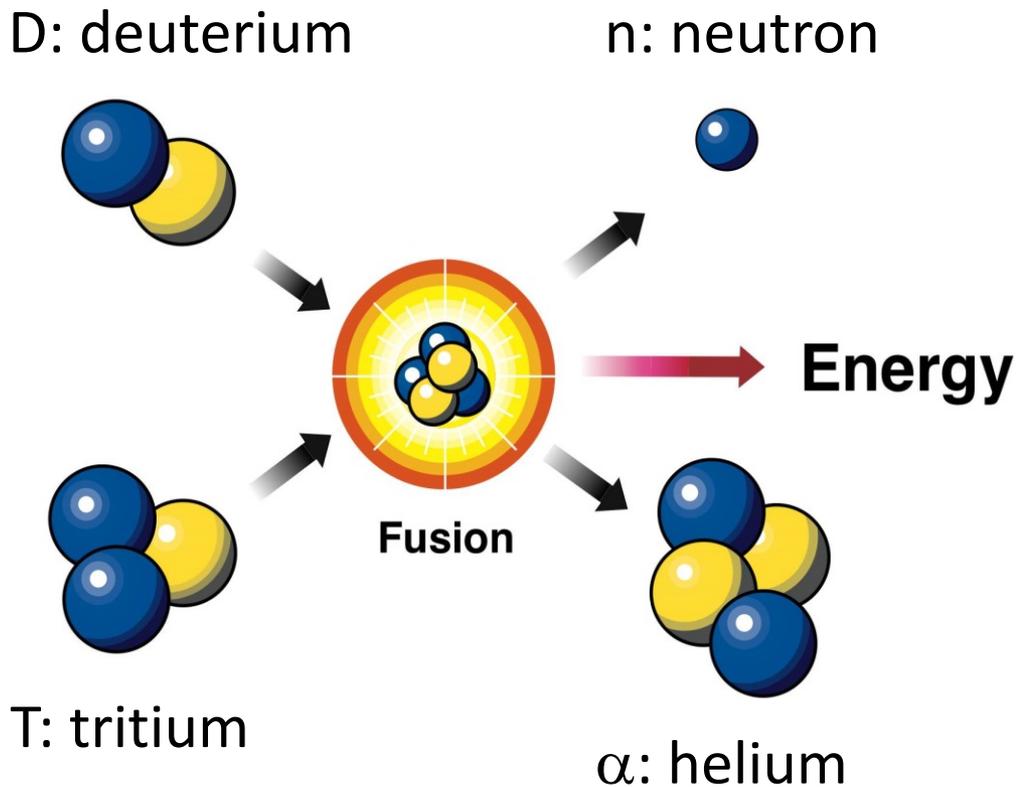

Plasma in other fields (e.g. medicine)

What is fusion?

"D-T" fusion reaction:

High energy gain
 $\approx 1000 \times$

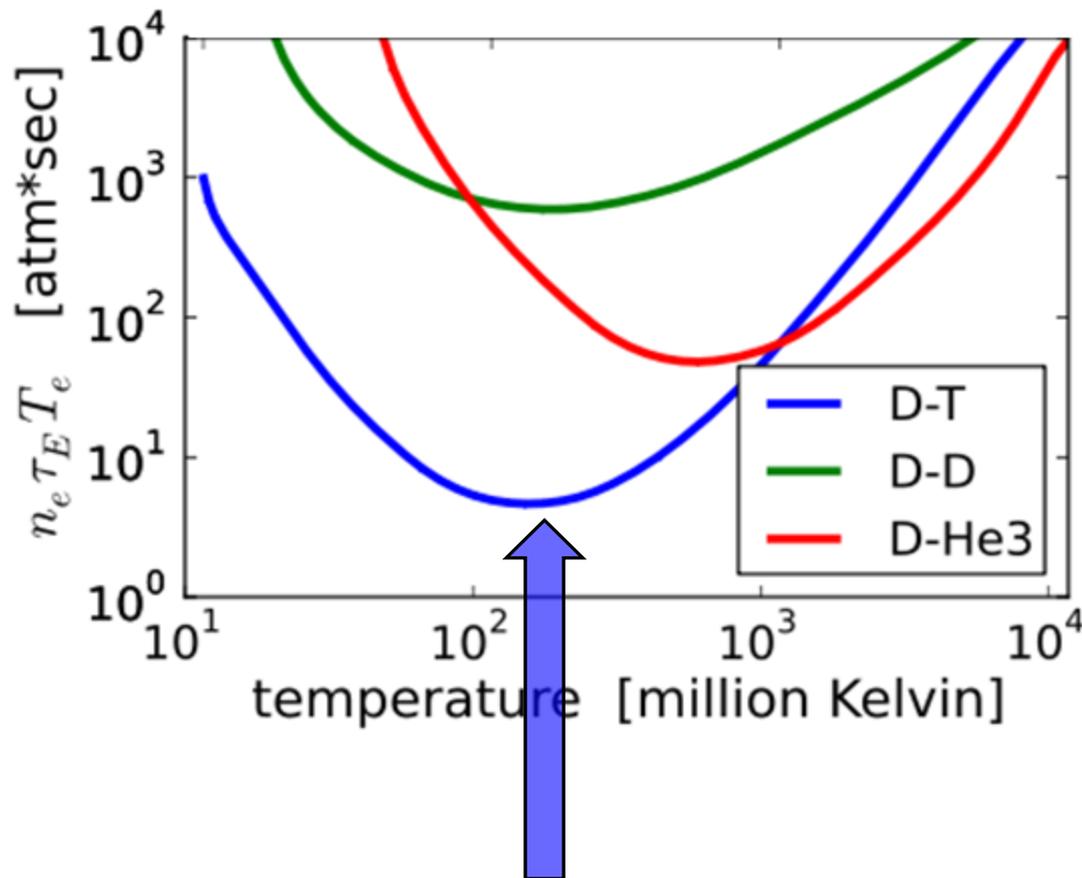

$$E = mc^2$$

Advantages of fusion: safe, sustainable, high energy density, environmentally attractive

- **Cannot have runaway reaction**
 - Only small amount of fuel present
 - If particles cool, fusion stops
- **Abundant fuel supply**
 - D from seawater: HDO, D/H = 1/6400
 - T bred from lithium in earth's crust
- **High energy density**
 - 1 liter water = 500 liters gasoline
- **Waste short-lived, low-level**
- **No CO₂ production**

Fusion requires very high temperatures

Fusion
difficulty
(pressure ×
confinement)

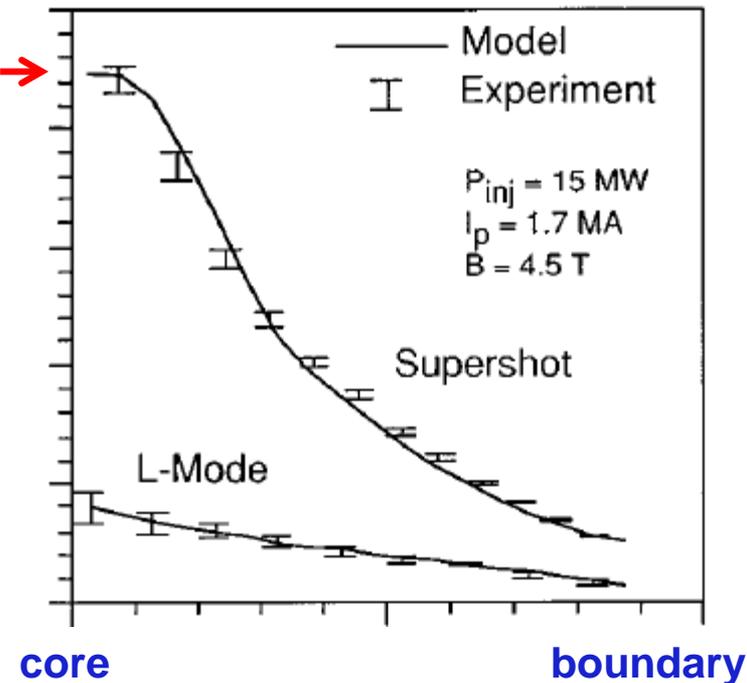

- Fusion is easiest here at 200 million °C (!!)
- Requires lowest pressure nT and energy confinement time τ_E
- Minimum fusion “triple-product” value: 8 atmosphere-seconds

Magnetic fusion has already achieved the necessary very high temperatures!

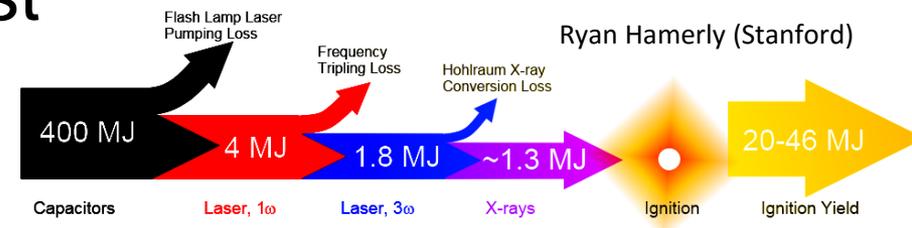

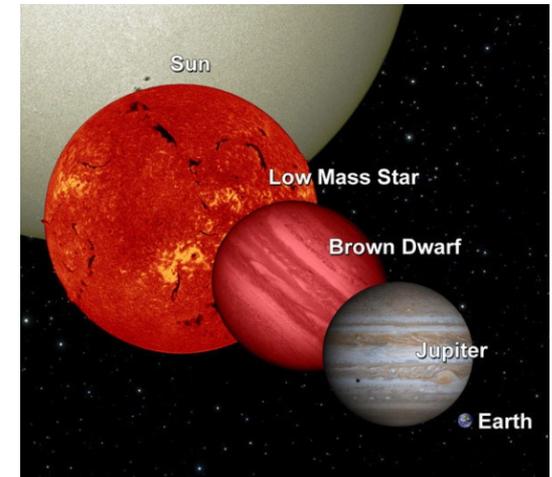

TFTR at PPPL (1990's)

~250 million C →

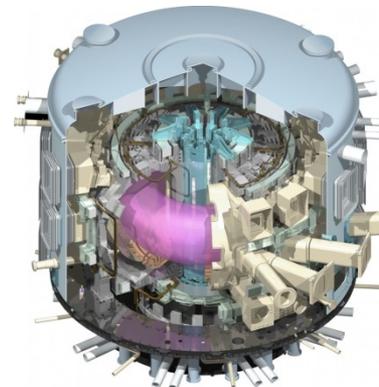

Magnetic fusion is arguably closest to ultimate goal of electricity generation

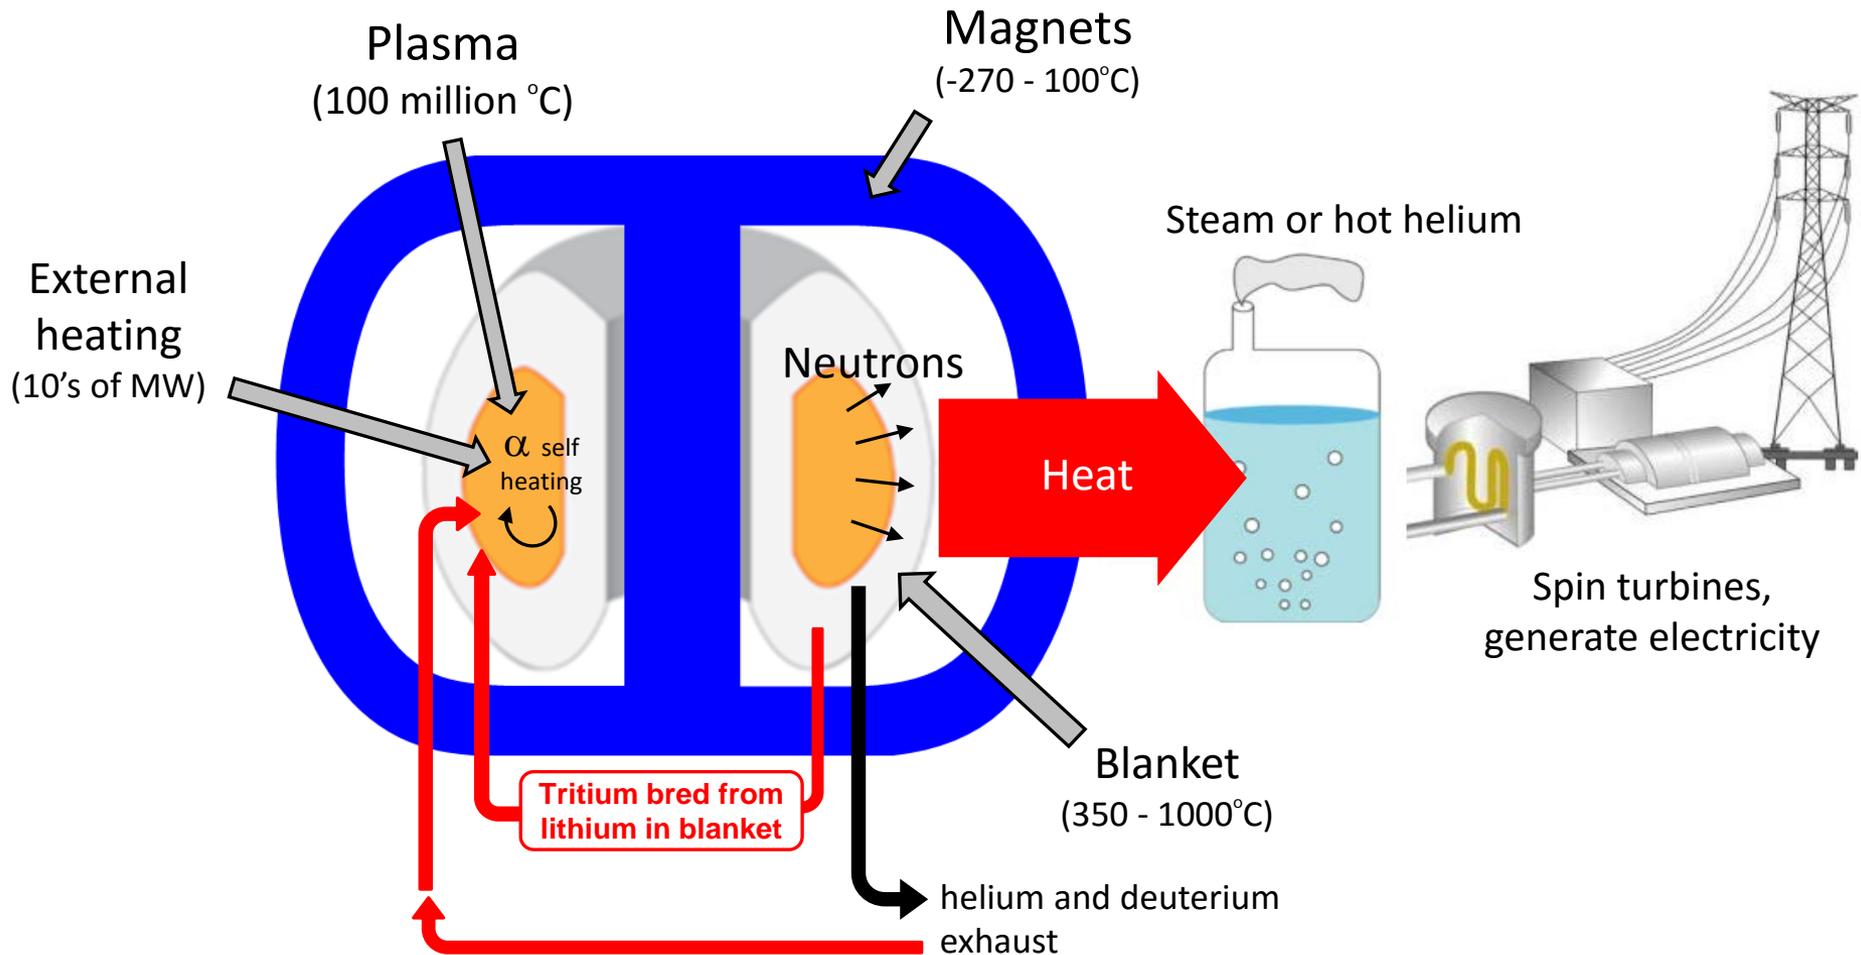

- Gravitational confinement fusion requires large device
 - Need 7-8% of mass of our sun
 - Approximately 10x diameter of Earth
- Laser fusion ala NIF at best has $E_{\text{fusion}} / E_{\text{electrical}} \sim 5\%$
 - So far, 0.004% efficient
- Magnetic fusion in ITER:
 - Goal: 500MW fusion power for $\leq 600\text{MW}$ electrical input for 400s
 - Industrial levels of fusion power

14kJ fusion yield achieved

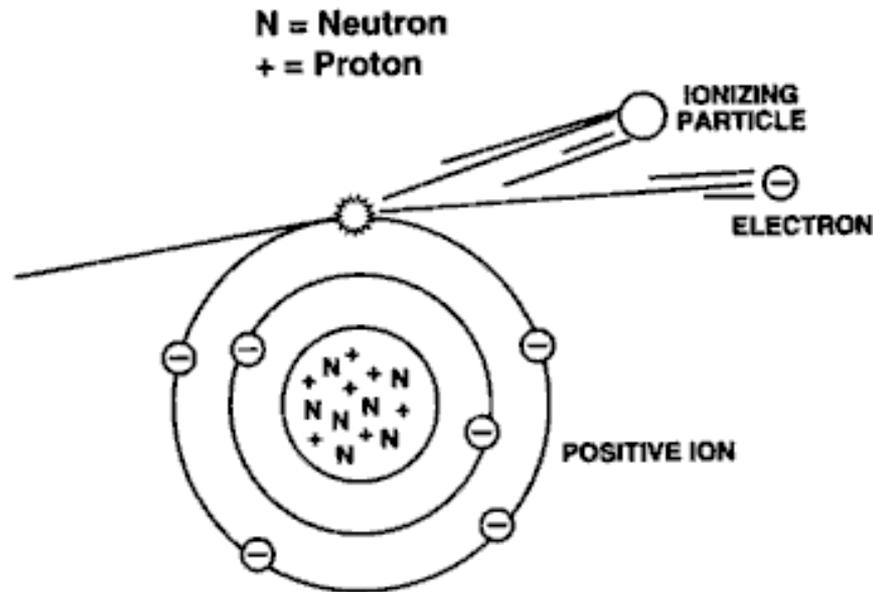

How would magnetic fusion make electricity?

How do we confine plasma?

Plasma is a gas of charged particles:
“Soup” of negatively charged electrons, positive ions

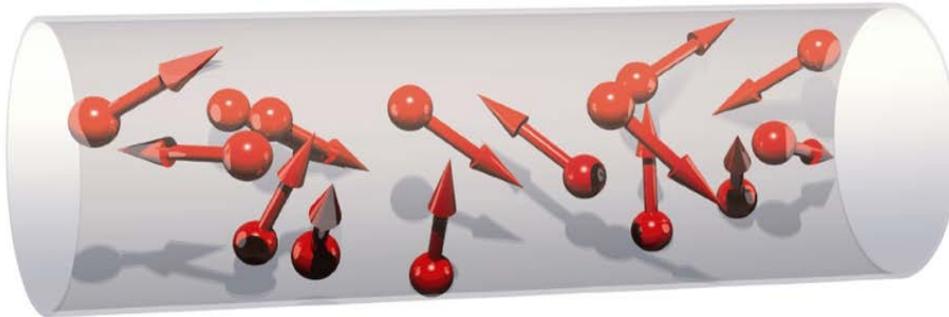

- At fusion temperatures, particles are so energetic that negatively charged (-) electrons are stripped from neutral atom leaving positively charged (+) ions

- One benefit of plasma state: charged particle motion can be manipulated by electric and magnetic fields

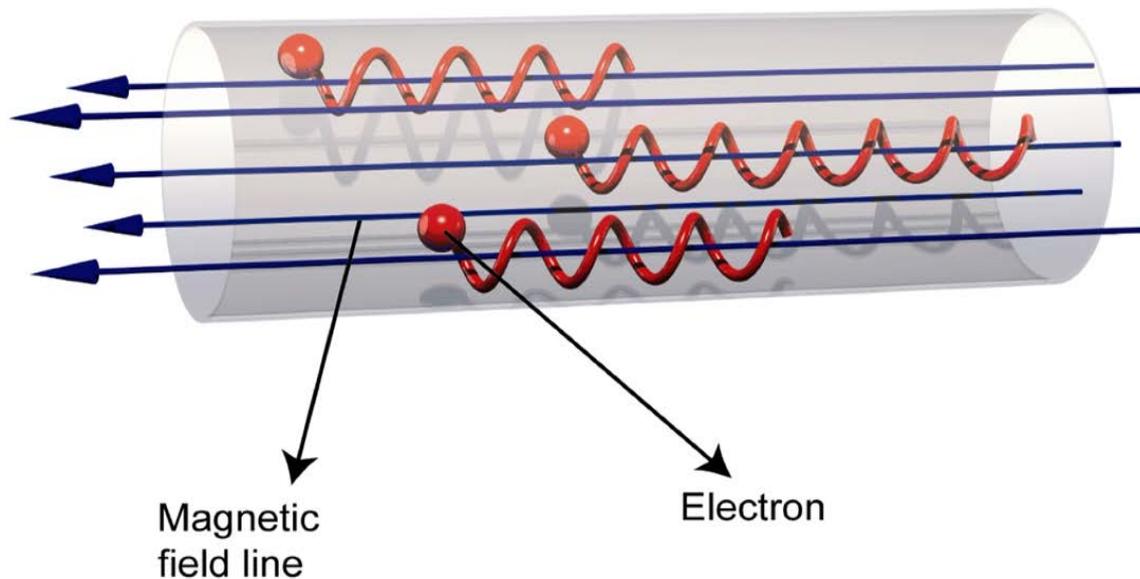

Charged particles confined by magnetic fields

No magnetic field

- No magnetic field: Charged particles move freely in all directions

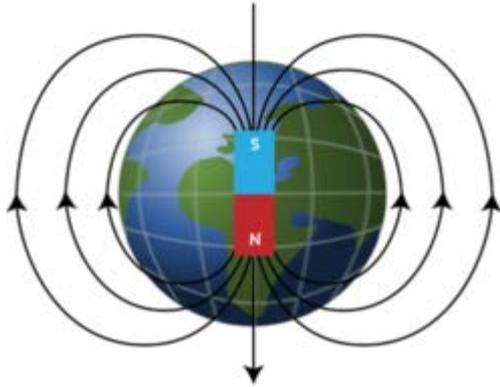

With magnetic field

- Charged particles spiral around magnetic field “arrows”, but move freely along the field
- **Magnetic fusion goal: make field so particles never touch walls**

Example magnetic fields in units of Tesla [T]

Earth: $\sim 5 \times 10^{-5}$ T

Refrigerator magnets
 $\sim 1-5 \times 10^{-3}$ T

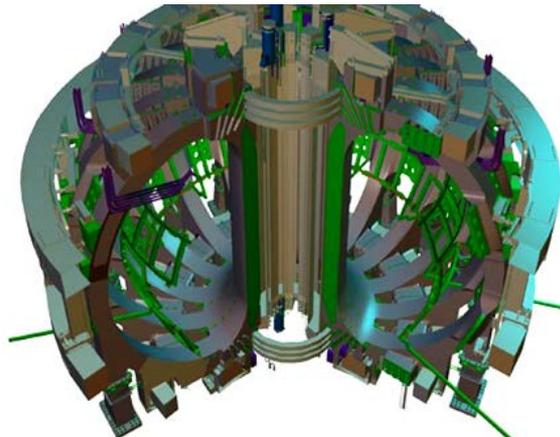

PPPL's NSTX-U: 1 T

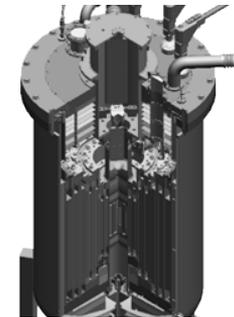

MRI: 0.5-3 T

ITER: 5.3 T

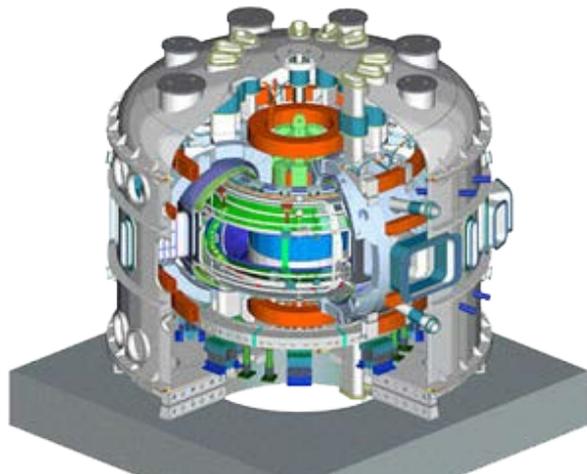

World Record: 100 T
Non-destructive - for few milliseconds

National High Magnetic Field Laboratory

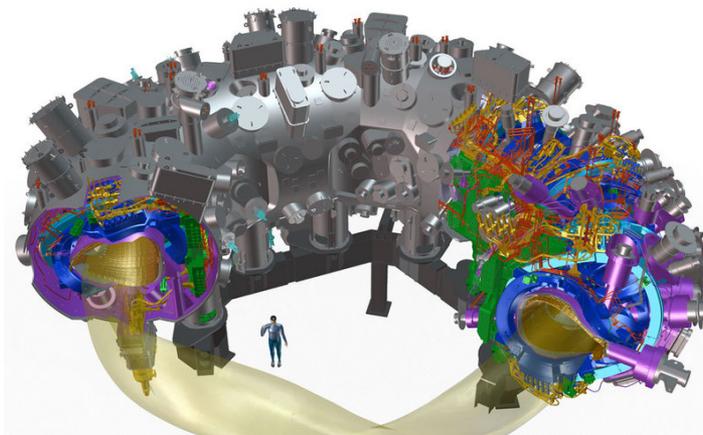

Tokamaks and stellarators are the leading configurations in magnetic fusion

Superconducting tokamak

KSTAR (South Korea)

Superconducting stellarator

W7-X (Germany) – 1st run campaign in 2016

- Tokamak advantages:

- Best confinement, closest to “breakeven”
- Simpler planar coils and power/particle exhaust

- Disadvantages:

- Must drive multi-mega-ampere plasma current
- More prone to rapid loss of plasma = “disruption”

- Stellarator advantages:

- No plasma current drive necessary
- More stable, steady-state

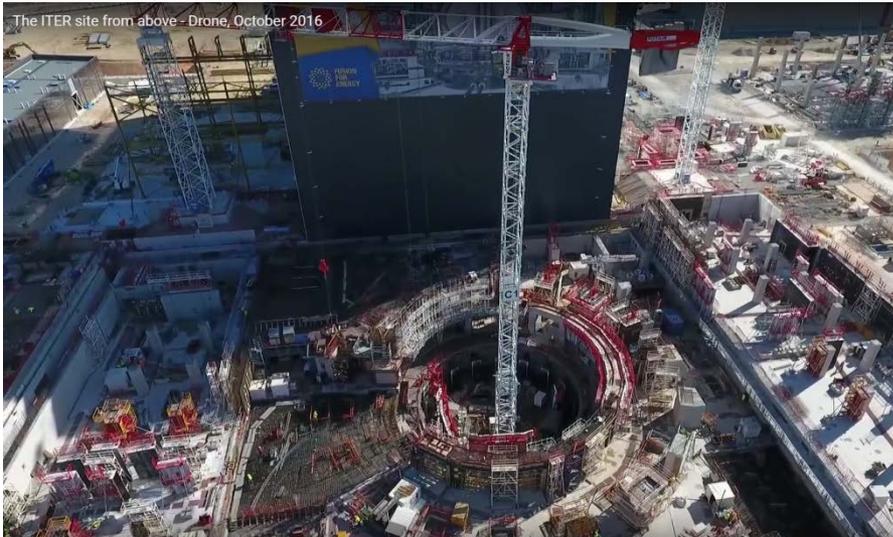

- Disadvantages:

- More complex coils and exhaust
- **Confinement < tokamaks (so far...)**

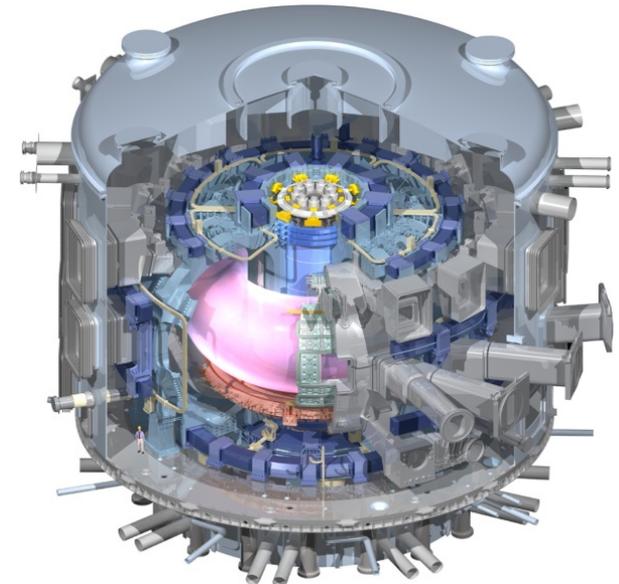

ITER will be first device to access “burning plasma”

- Burning plasma: majority of plasma heating power comes from fusion alpha particles from DT reactions
 - DT reaction energy split: 1/5 in alphas, 4/5 in neutrons
- ITER goal $Q = P_{\text{fusion}} / P_{\text{external heating}} = 10$
- $Q = 10 \rightarrow P_{\text{alpha}} / P_{\text{external}} = 2$
- $P_{\text{alpha}} / P_{\text{alpha} + \text{external}} = 2 / 3 > 50\%$

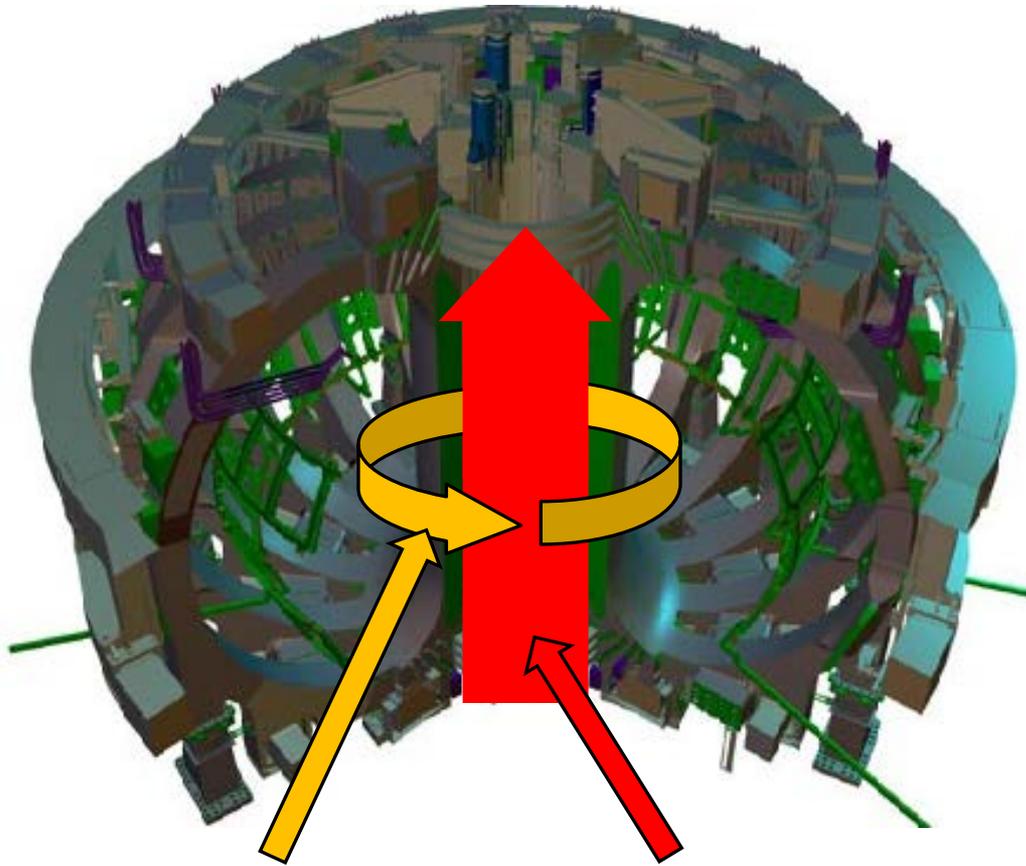

ITER under construction in Cadarache, France

$A=3.1$, $R=6.2\text{m}$, $B_T=5.3\text{T}$, $I_p=15\text{MA}$

ITER magnets will be largest ever built

Plasma current:
15 million amps

Toroidal field current
165 million amps

- 18 toroidal field magnets
- 12 Tesla at coil
- Weight: 6500 tons
- 80,000 km of Nb₃Sn superconducting strand in total length

Size of ITER driven largely by plasma confinement

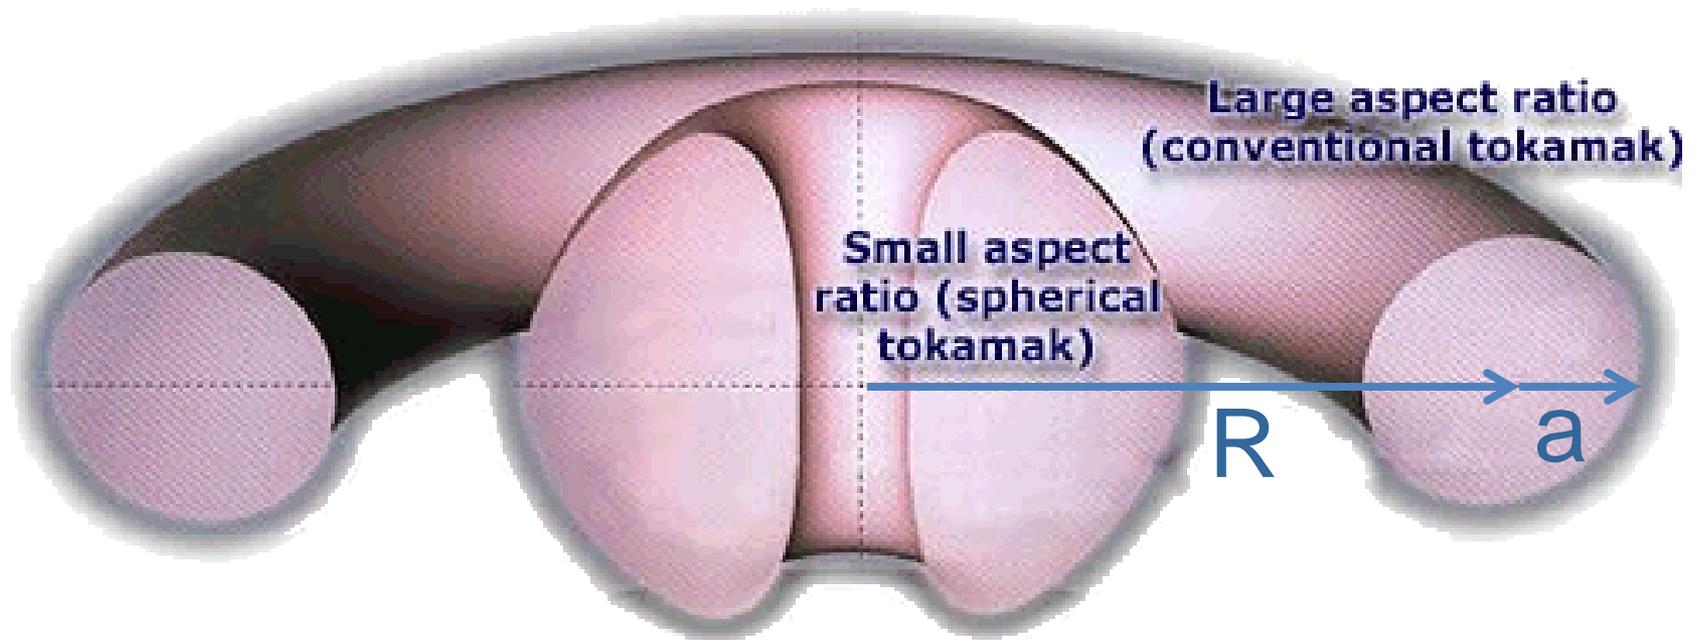

- Energy confinement scales with plasma current
- Large plasma current requires large toroidal field and/or plasma size for plasma to remain stable
- Current and confinement both scale with size
- **Can we make smaller devices with better confinement and smaller or cheaper magnets?**
- Such questions motivate exploring alternatives...

How might we possibly improve
the conventional tokamak?

Aspect ratio is important free parameter

$$\text{Aspect ratio } A = R / a$$

R = major radius a = minor radius

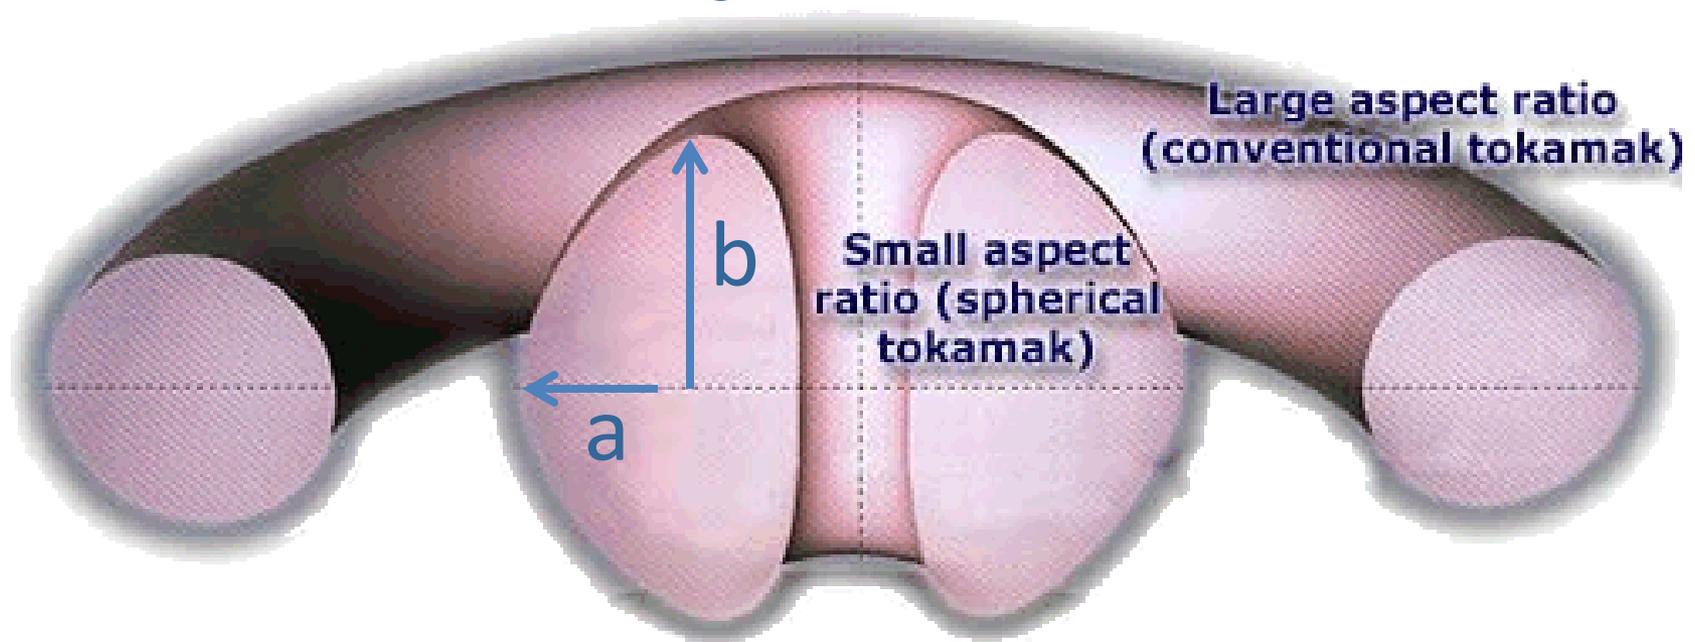

Spherical torus/tokamak (ST) has $A = 1.1-2$

Conventional tokamak typically $A = 3-4$

STs have higher natural elongation

Elongation $\kappa = b / a$

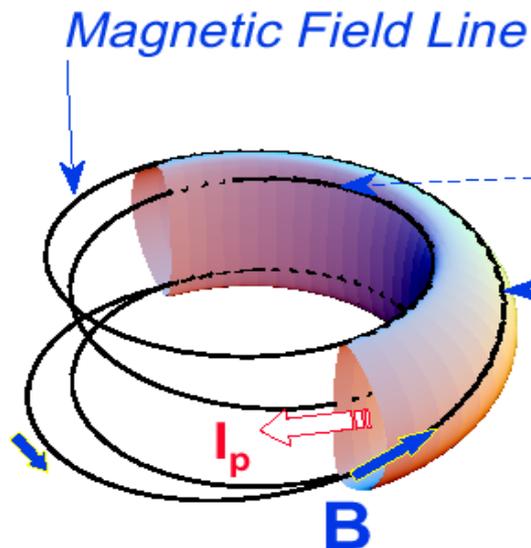

b = vertical $\frac{1}{2}$ height a = minor radius

Higher elongation improves stability, confinement

Favorable average curvature improves stability

Tokamak

$$A \sim 3$$

$$\kappa = 1.5-2$$

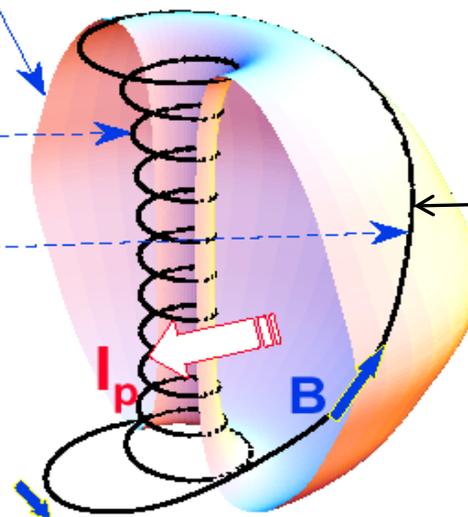

$$\beta_T = 3-10\%$$

Stable

Unstable

Magnetic Surface

ST

$$A \sim 1.5$$

$$\kappa = 2-3$$

$$\beta_T = 10-40\%$$

Plasma spends less time in unstable curvature region

Aspect Ratio $A = R/a$

Elongation $\kappa = b/a$

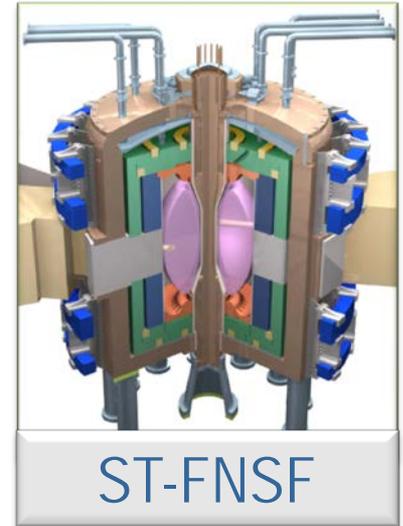

Toroidal beta $\beta_T = \langle p \rangle / (B_{T0}^2/2\mu_0)$

Fusion technology development is major challenge

Fusion Nuclear Science Facility (FNSF) could aid development

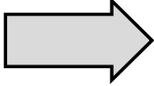

Need to develop reliable and qualified nuclear and other components which are unique to fusion:

- Divertor, plasma facing components for exhaust
- Blanket and Integral First Wall
- Vacuum Vessel and Shield
- Tritium Fuel Cycle
- Remote Maintenance Components

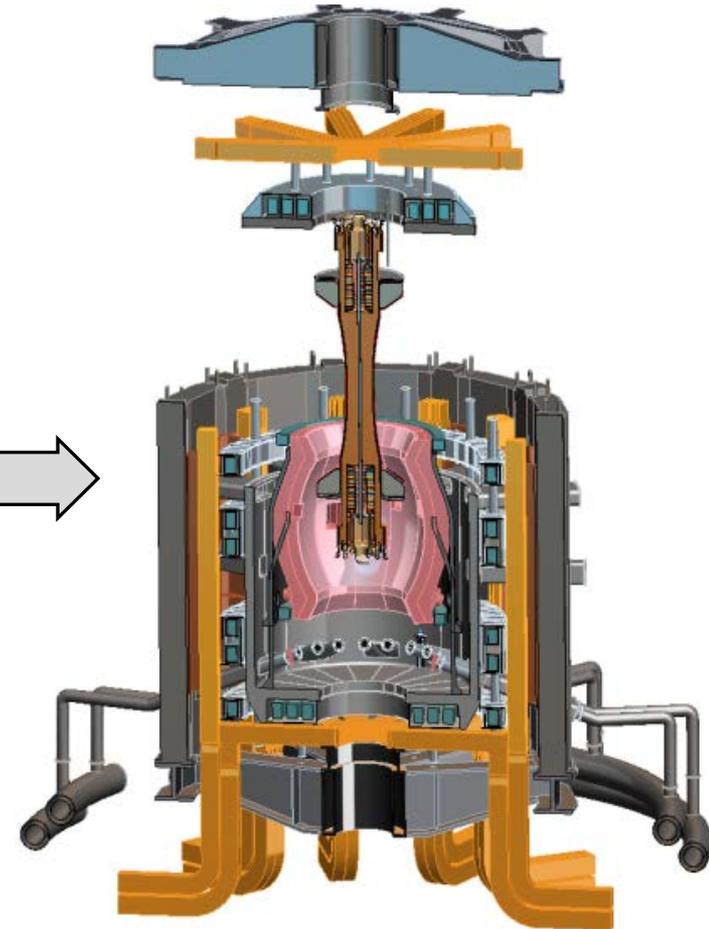

- Without R&D, fusion components could fail prematurely, requiring long repair/down time.
- This would cripple power plant operation
- FNSF can help develop reliable fusion components
- Such FNSF facilities must be: **modest cost, low T, and reliable**

Design studies show ST potentially attractive as FNSF

- Projected to access high neutron wall loading at moderate R, P_{fusion}
 - $W_n \sim 1\text{-}2 \text{ MW/m}^2$, $P_{\text{fus}} \sim 50\text{-}200\text{MW}$, $R \sim 0.8\text{-}1.8\text{m}$
- Modular, simplified maintenance 
- Tritium breeding ratio (TBR) near 1
 - Requires sufficiently large R, careful design

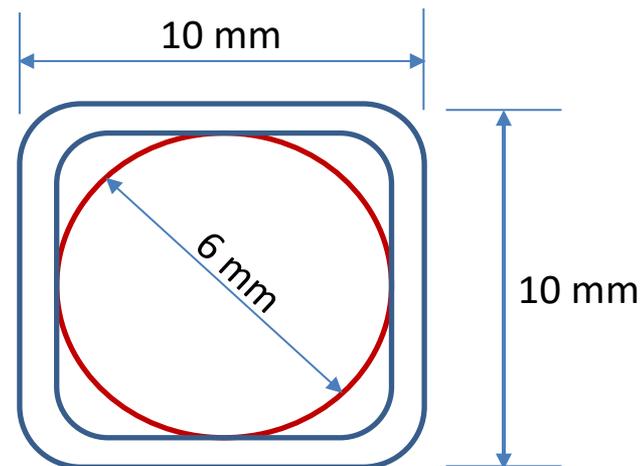

PPPL ST-FNSF concept

HTS cables using REBCO tapes achieving high winding pack current density at high B_T

Conductor on Round Core Cables (CORC)

$J_{WP} \sim 70 \text{ MA/m}^2$ 19T

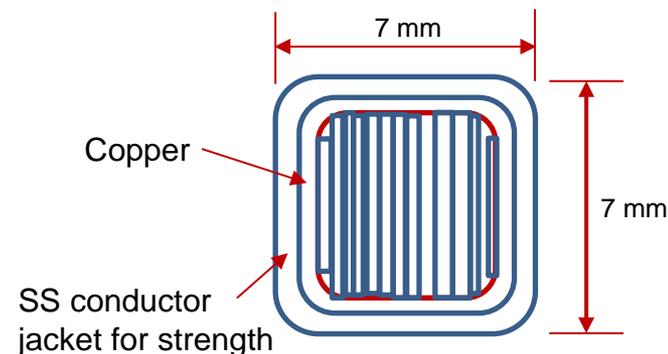

7 kA CORC (4.2K, 19 T) cable

Base cable: 50 tapes YBCO Tapes with 38 mm substrate (Van Der Laan, HTS4Fusion, 2015)

Higher J_{cable} HTS
cable concepts
under development:

Base Conductor
He Gas Cooled
8kA,
 $J_{WP} \sim 160 \text{ MA/m}^2$

High current density HTS cable motivates consideration of low-A tokamak pilot plants

- ITER-like TF constraints:

- $J_{WP} = 20 \text{ MA/m}^2$, $B_{\text{max}} \leq 12 \text{ T}$

- $P_{\text{fusion}} \leq 130 \text{ MW}$

- $P_{\text{net}} < -90 \text{ MW}$

- $J_{WP} \sim 30 \text{ MA/m}^2$, $B_{\text{max}} \leq 19 \text{ T}$

- $P_{\text{fusion}} \sim 400 \text{ MW}$

- **Small P_{net} at $A = 2.2 - 3.5$**

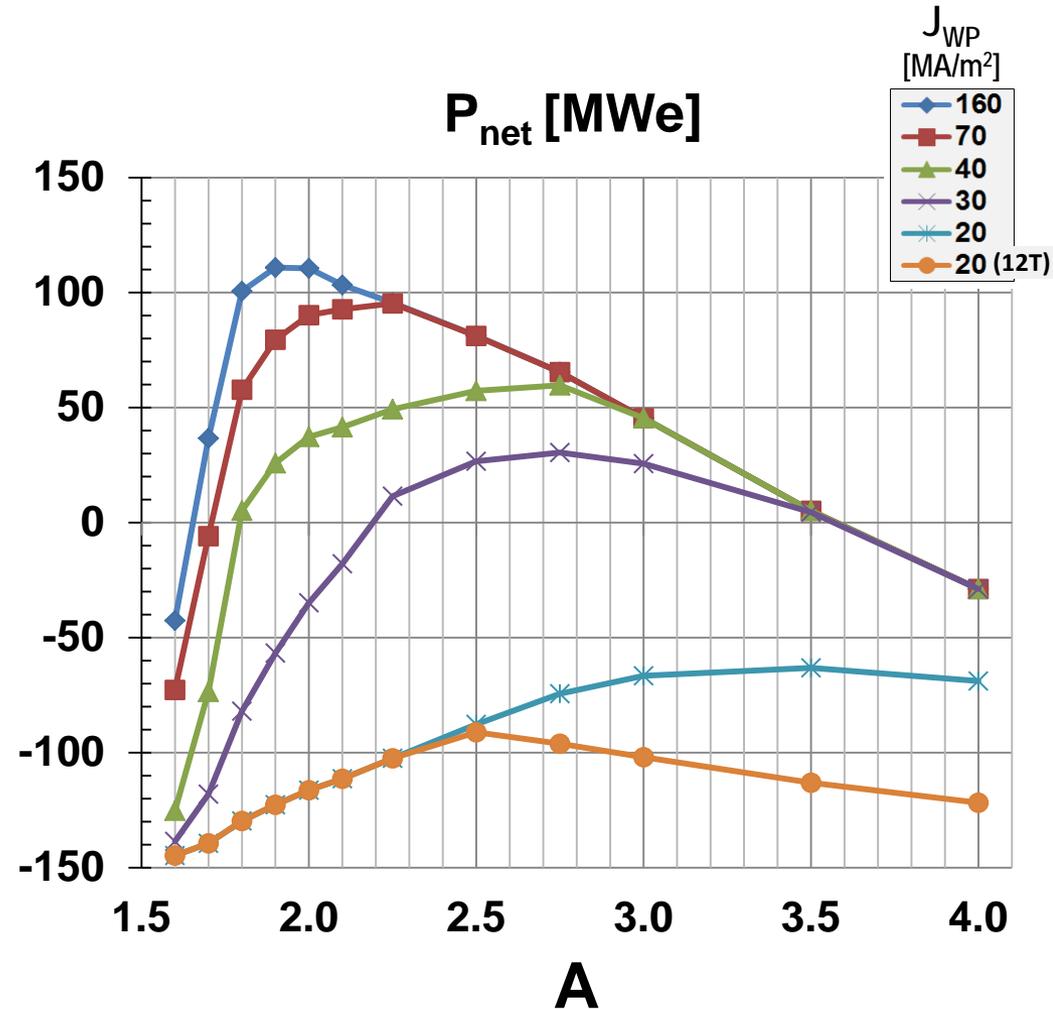

- $J_{WP} \geq 70 \text{ MA/m}^2$, $B_{\text{max}} \leq 19 \text{ T}$

- $P_{\text{fusion}} \sim 500 - 600 \text{ MW}$

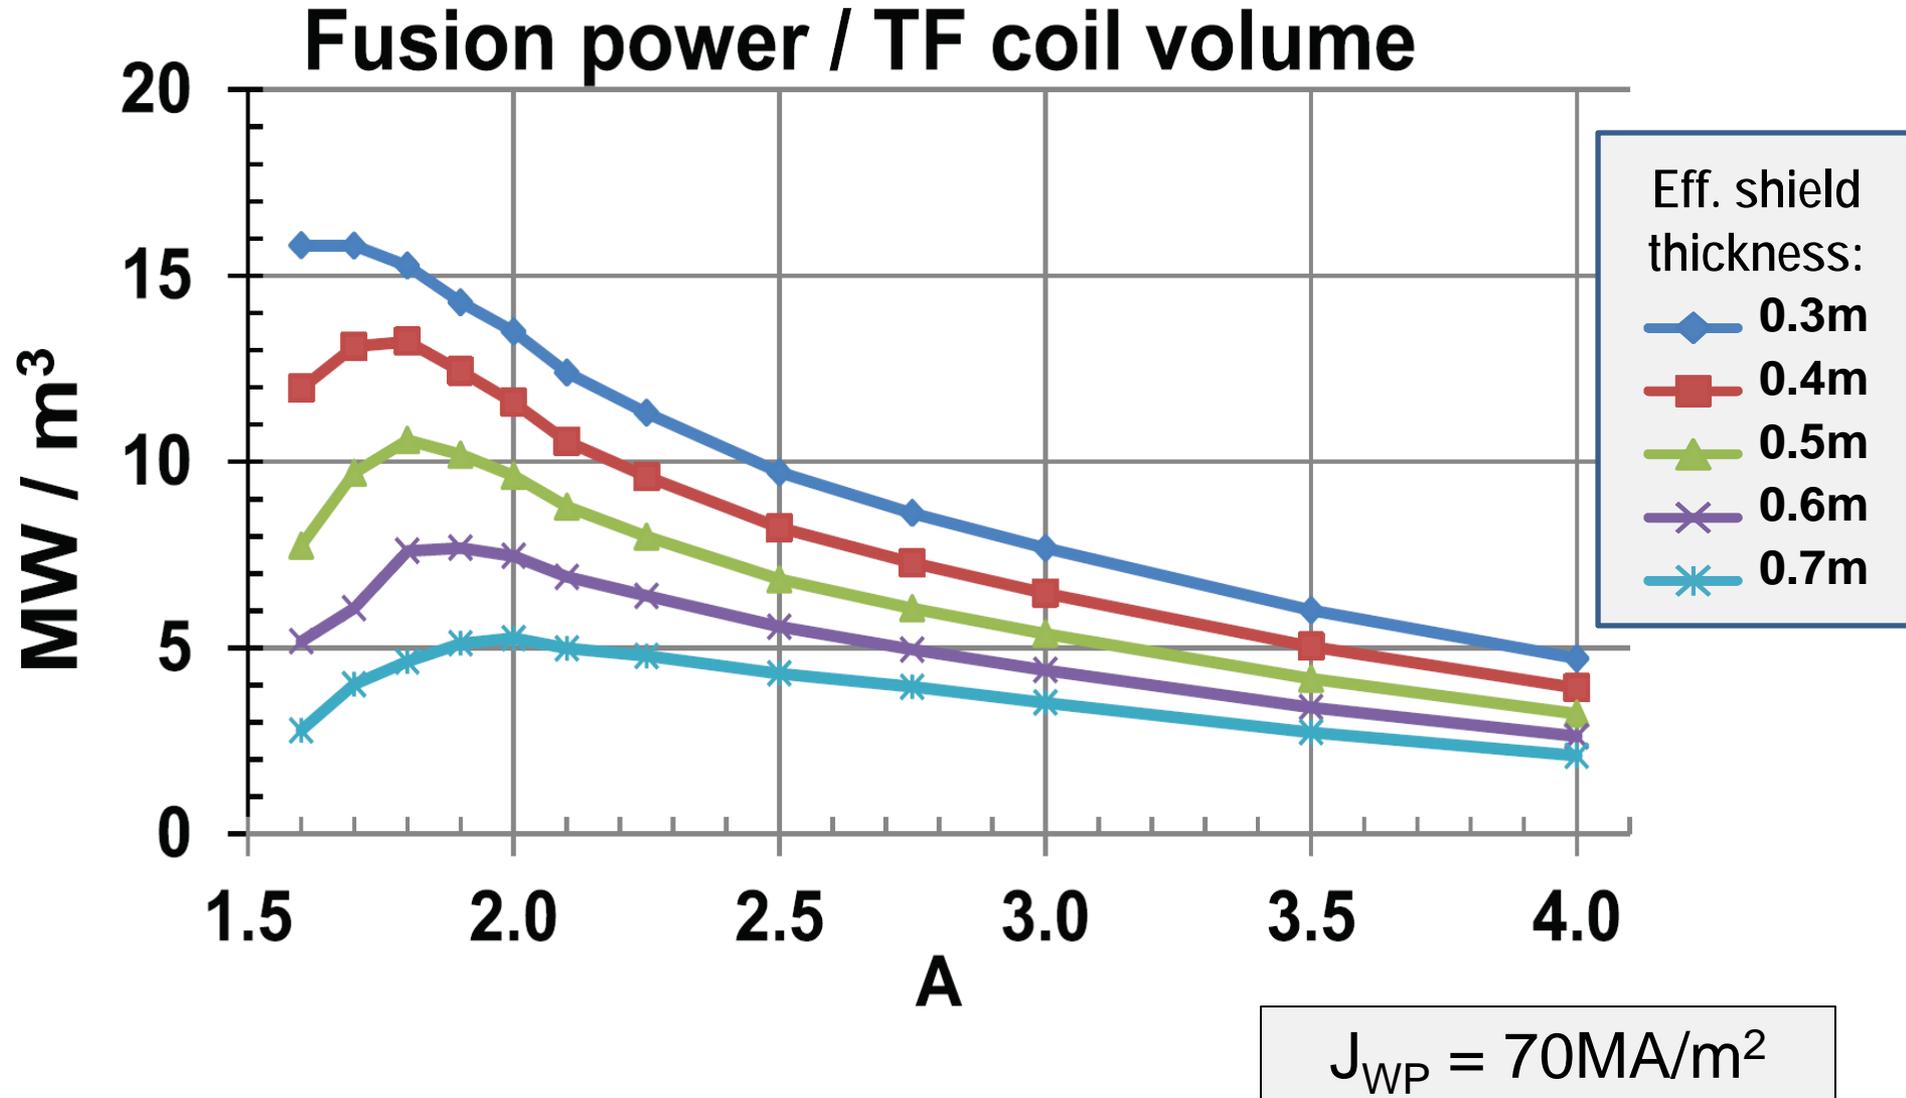

- **$P_{\text{net}} = 80 - 100 \text{ MW}$ at $A = 1.9 - 2.3$**

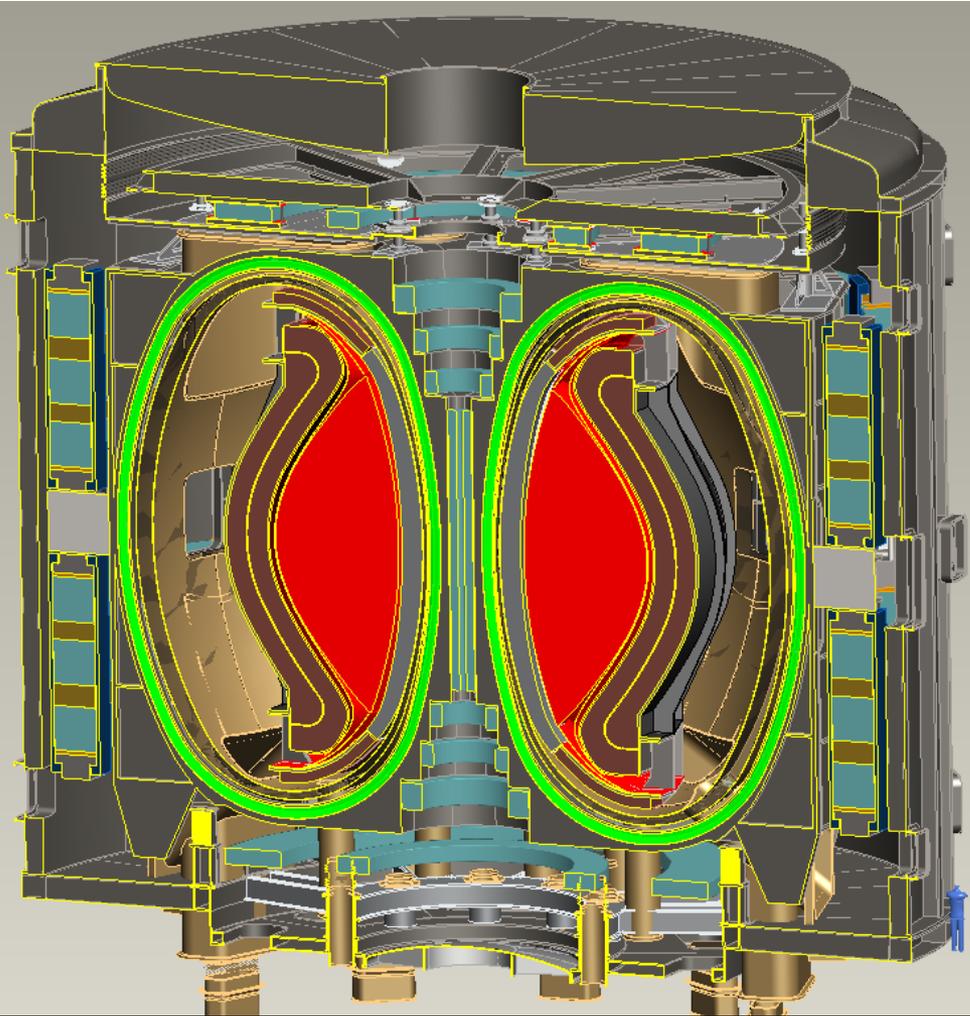

$A \sim 2$ attractive at high J_{WP}

$A \leq 2$ maximizes TF magnet utilization

A=2, R₀ = 3m HTS-TF FNSF / Pilot Plant

Cryostat volume ~ 1/3 of ITER

$B_T = 4T$, $I_p = 12.5MA$

$\kappa = 2.5$, $\delta = 0.55$

$\beta_N = 4.2$, $\beta_T = 9\%$

$H_{98} = 1.8$, $H_{Petty-08} = 1.3$

$f_{gw} = 0.80$, $f_{BS} = 0.76$

Startup I_p (OH) ~ 2MA

$J_{WP} = 70MA/m^2$

$B_{T-max} = 17.5T$

No joints in TF

Vertical maintenance

$P_{fusion} = 520 MW$

$P_{NBI} = 50 MW$, $E_{NBI} = 0.5MeV$

$Q_{DT} = 10.4$

$Q_{eng} = 1.35$

$P_{net} = 73 MW$

$\langle W_n \rangle = 1.3 MW/m^2$

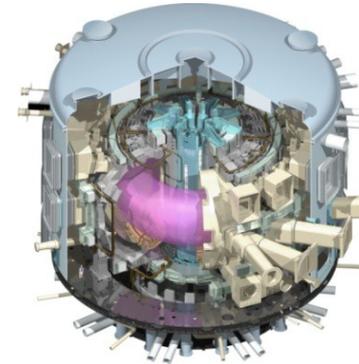

Peak n-flux = 2.4 MW/m²

Peak n-fluence = 7 MWy/m²

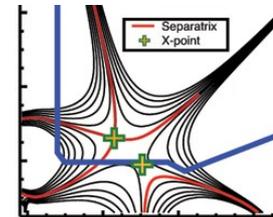

What are the goals of
NSTX Upgrade (NSTX-U)?

NSTX-U Mission Elements:

- Explore unique ST parameter regimes to advance predictive capability - for ITER and beyond
- Develop solutions for plasma-material interface (PMI)
- Advance ST as Fusion Nuclear Science Facility and Pilot Plant

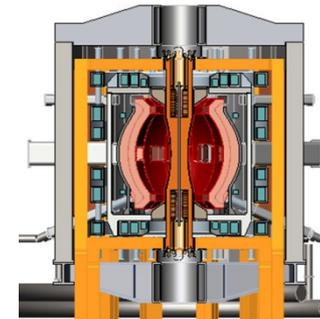

ITER

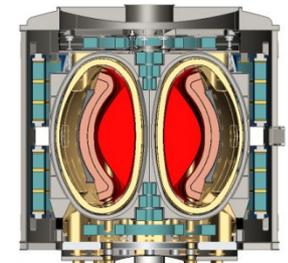

Snowflake/X

Liquid metals / Li

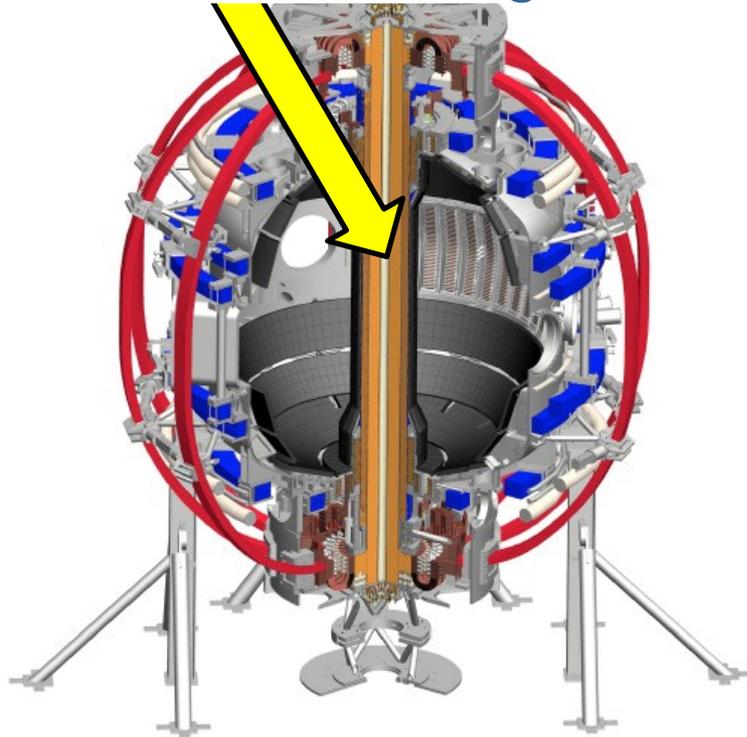

ST-FNSF /
Pilot-Plant

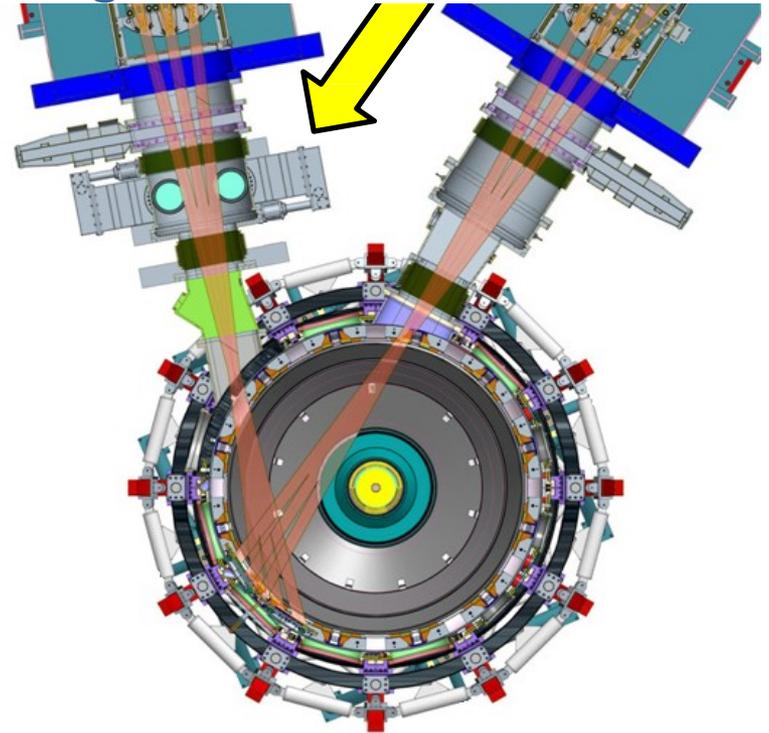

NSTX-U will access new physics with 2 major new tools:

1. New Central Magnet

Higher T, low ν^* from low to high β
→ Unique regime, study new transport and stability physics

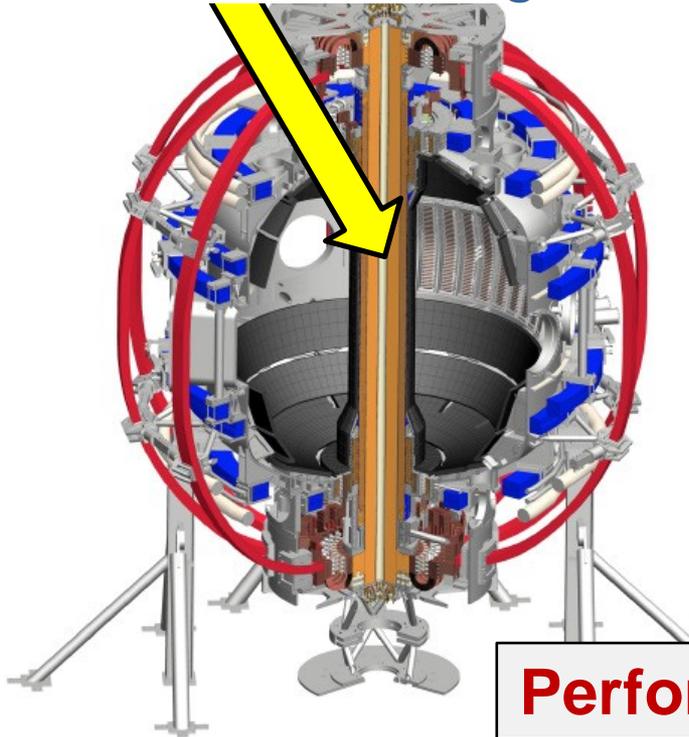

2. Tangential 2nd Neutral Beam

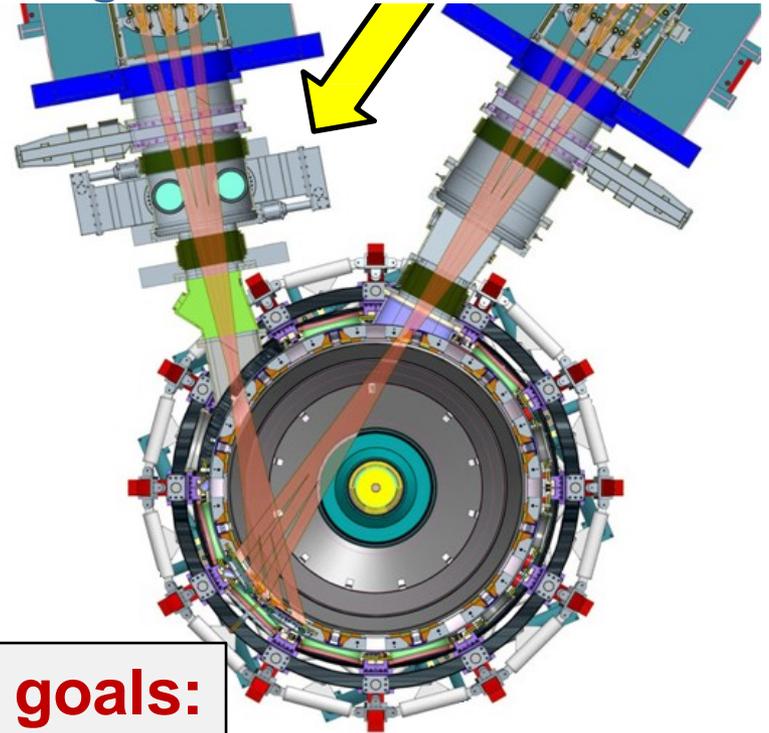

Full non-inductive current drive
→ Not demonstrated in ST at high- β_T
Essential for any future steady-state ST

NSTX-U will have major boost in performance

1. New Central Magnet

2. Tangential 2nd Neutral Beam

Performance goals:

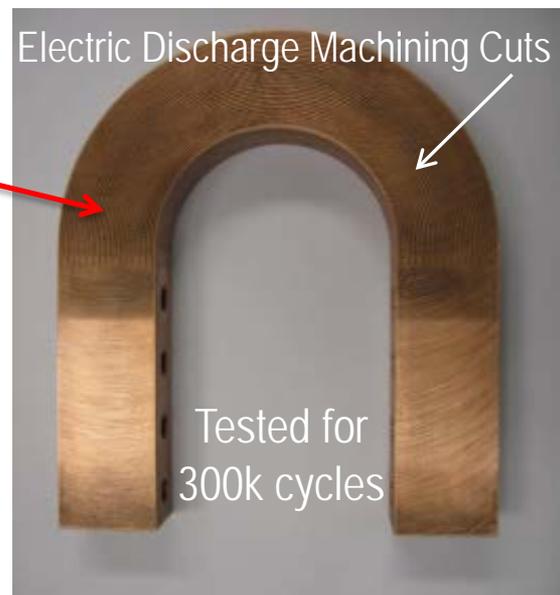

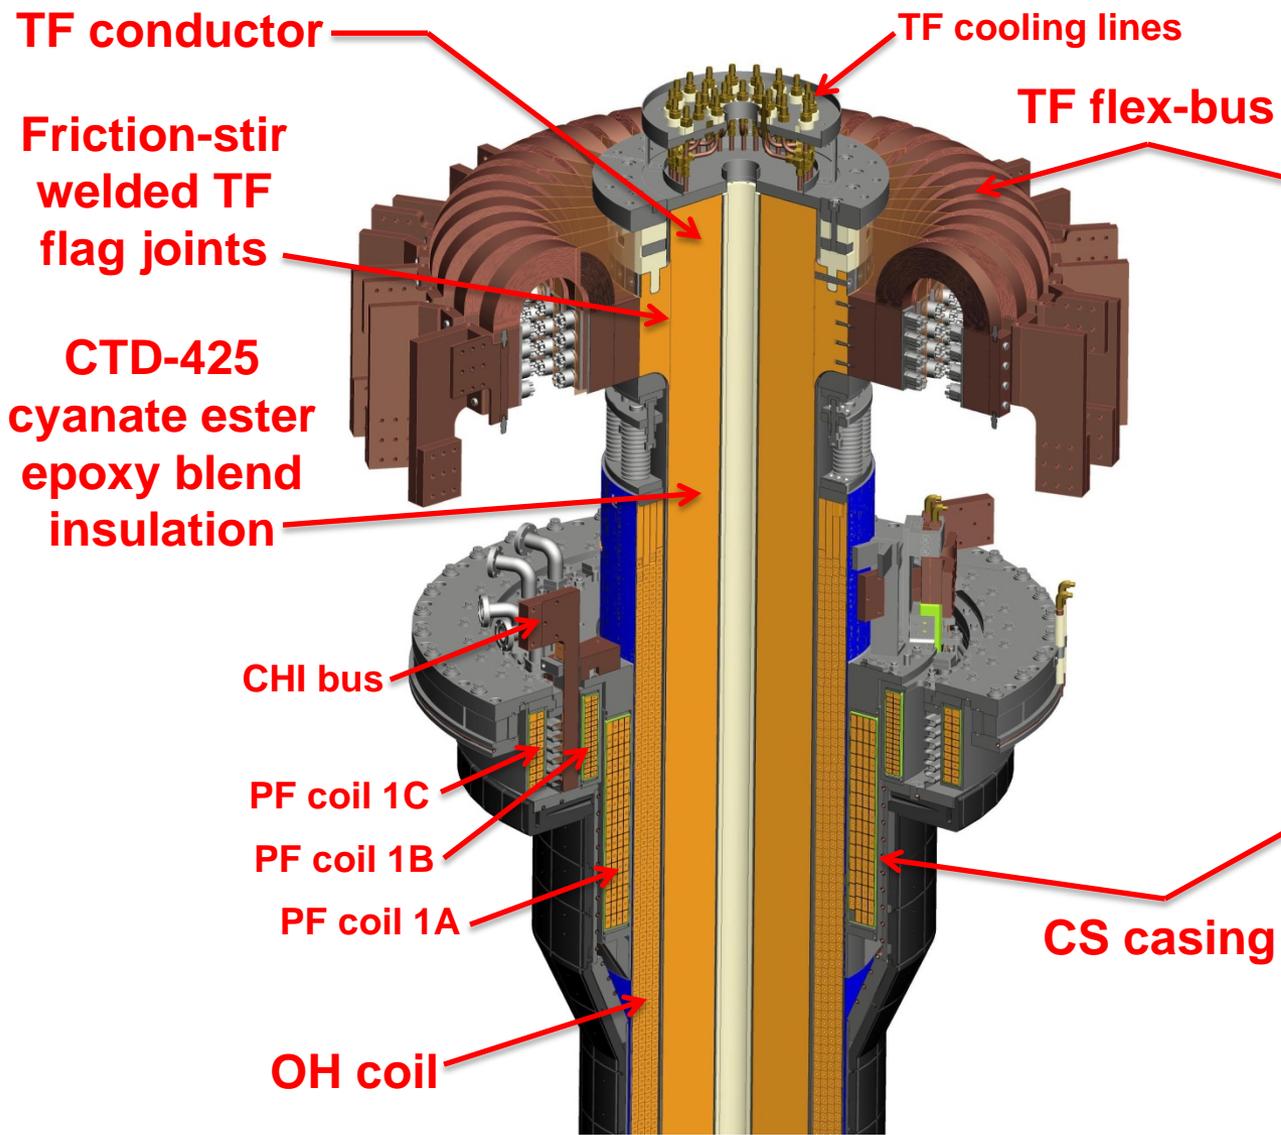

- 2× toroidal field (0.5 → 1T)
- 2× plasma current (1 → 2MA)
- 5× longer pulse (1 → 5s)

- 2× heating power (5 → 10MW)
 - Tangential NBI → 2× current drive efficiency
- 4× divertor heat flux (→ ITER levels)
- Up to 10× higher $nT\tau_E$ (~MJ plasmas)

How was NSTX-U constructed?

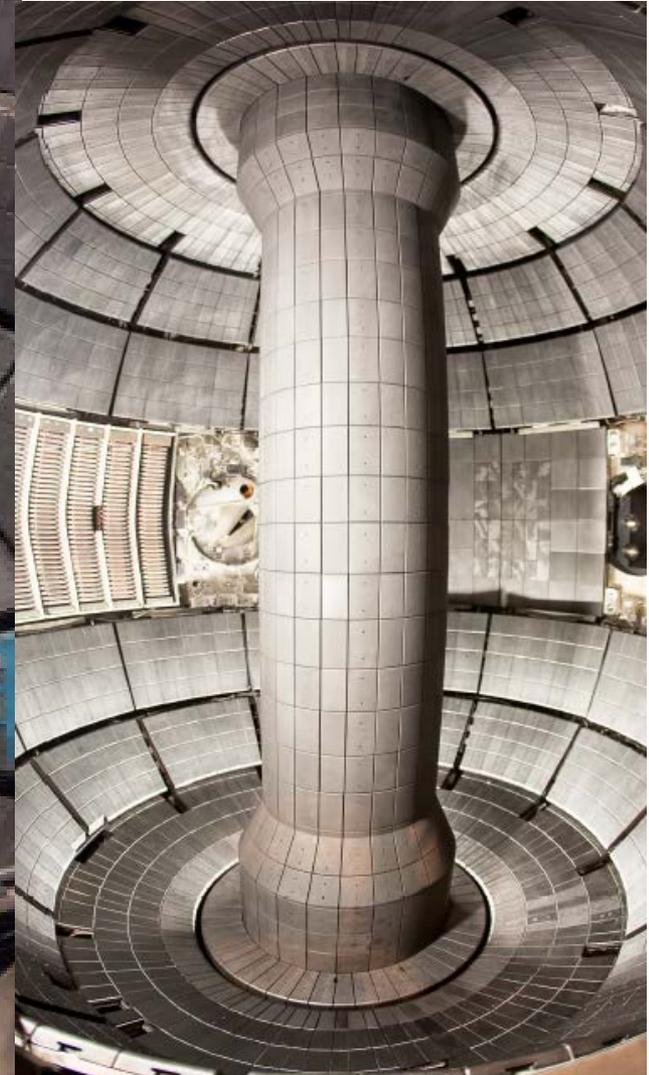

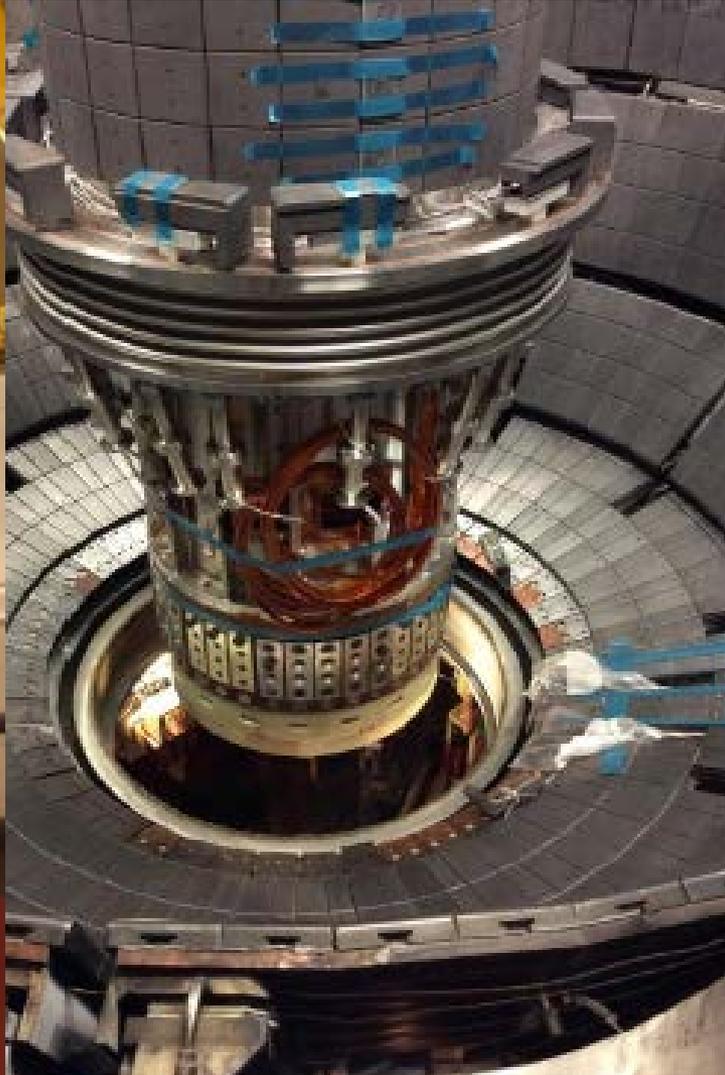

New center-stack designed to handle increased forces

Identical 36 TF conductors and innovative flex-bus design

New Center-Stack installed in NSTX-U

Vacuum pump-down achieved in January, 2015

Relocated 2nd NBI beam line box from the TFTR test cell into the NSTX-U test cell

TFTR NBI beam box and components successfully tritium decontaminated

Beam Box being lifted over NSTX

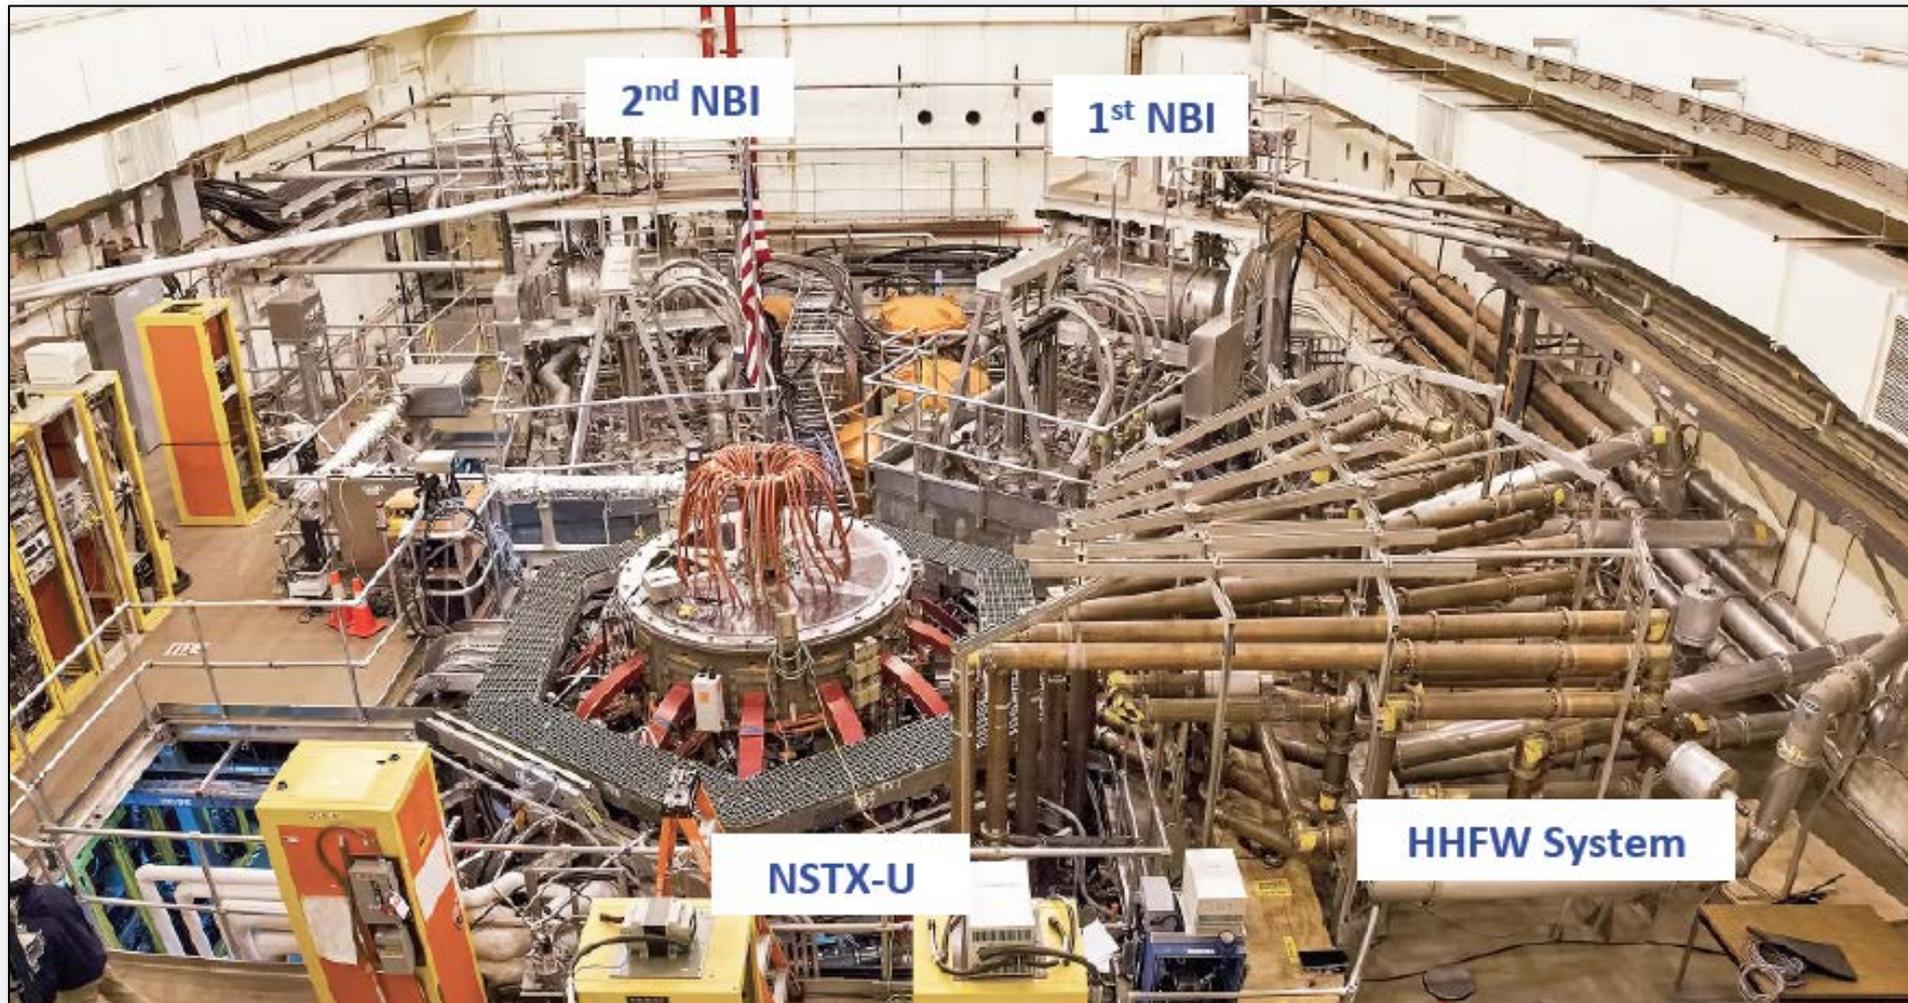

Beam Box placed in its final location and aligned

Beam Box being populated with components

NSTX Upgrade Project Completed September 2015

Test plasmas August 2015, Research plasmas December 2015

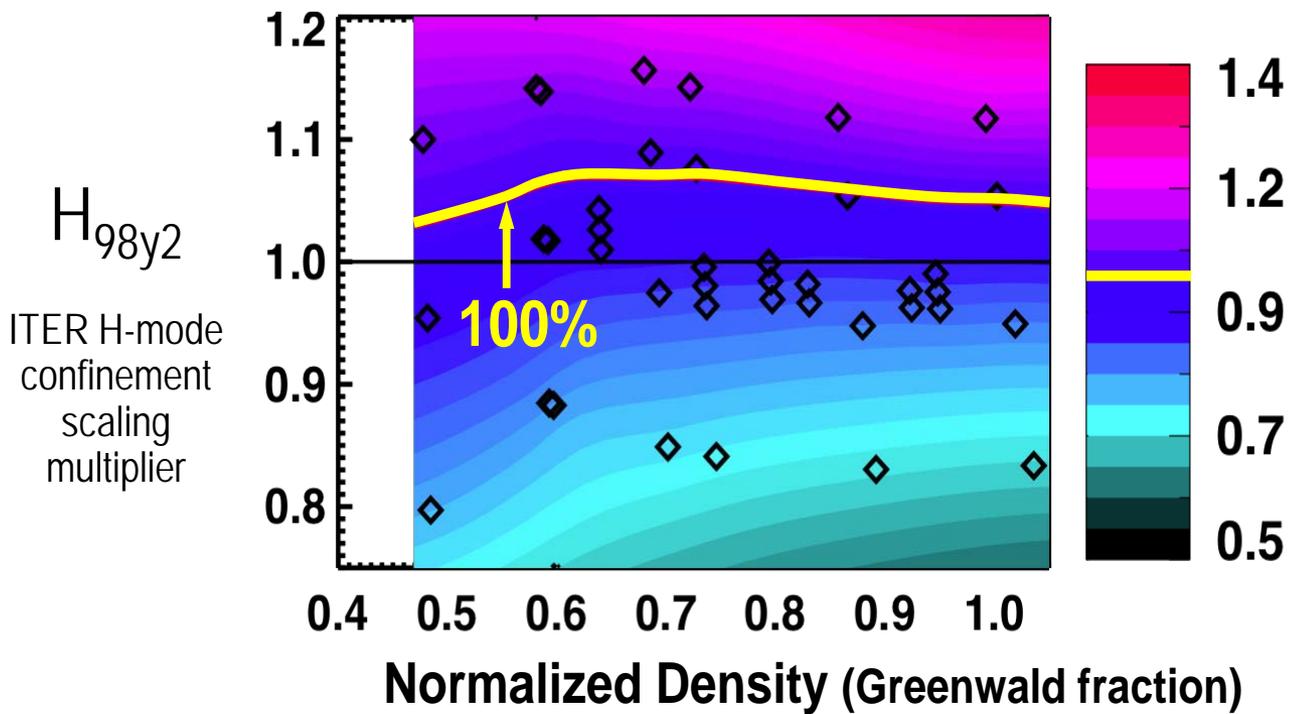

What key science questions
will NSTX-U address?

NSTX achieved 70% “transformer-less” current drive

Will NSTX-U achieve 100% as predicted by simulations?

TRANSP Contours of Non-Inductive Fraction

$I_p=1$ MA, $B_T=1.0$ T, $P_{NBI}=12.6$ MW

Steady-state operation required for ST, tokamak, or stellarator FNSF

I_p Start-up/Ramp-up Critical Issue for ST-FNSF

Compact ST-FNSF has
no/small central solenoid

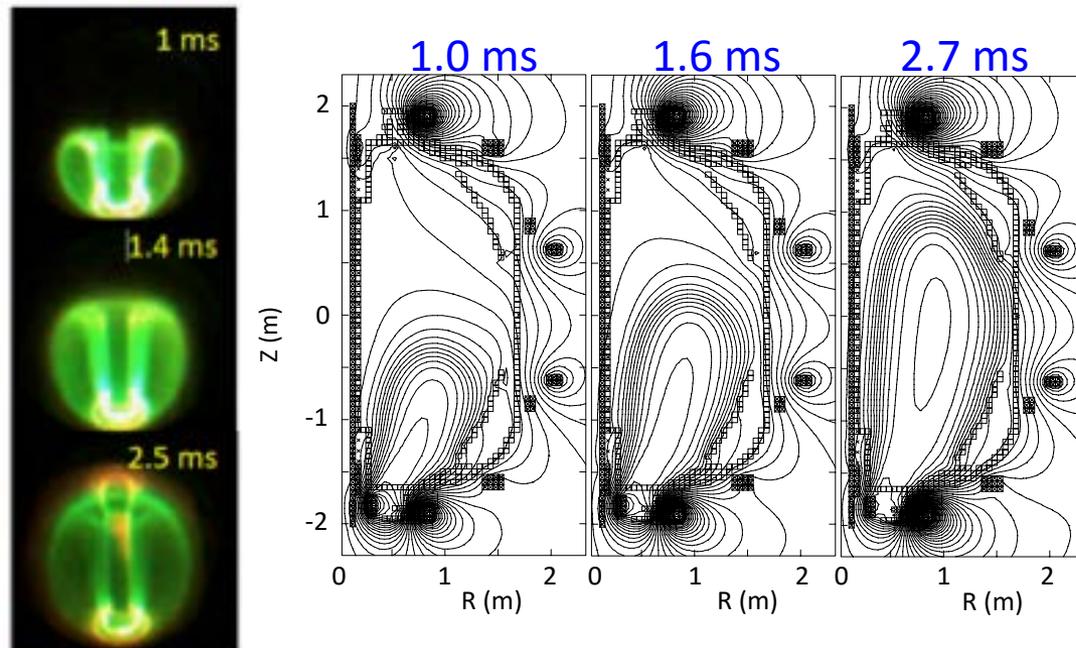

~ 1-2 MA of transformer-free start-up current needed for FNSF → 10-20% of total current

- Long-term major goal of NSTX-U: generate and sustain a high-performance plasma **without using any transformer** (this will not be easy...)

NSTX achieved 200kA (~20%) “transformer-less” start-up

Will NSTX-U achieve 400kA or more as per simulations?

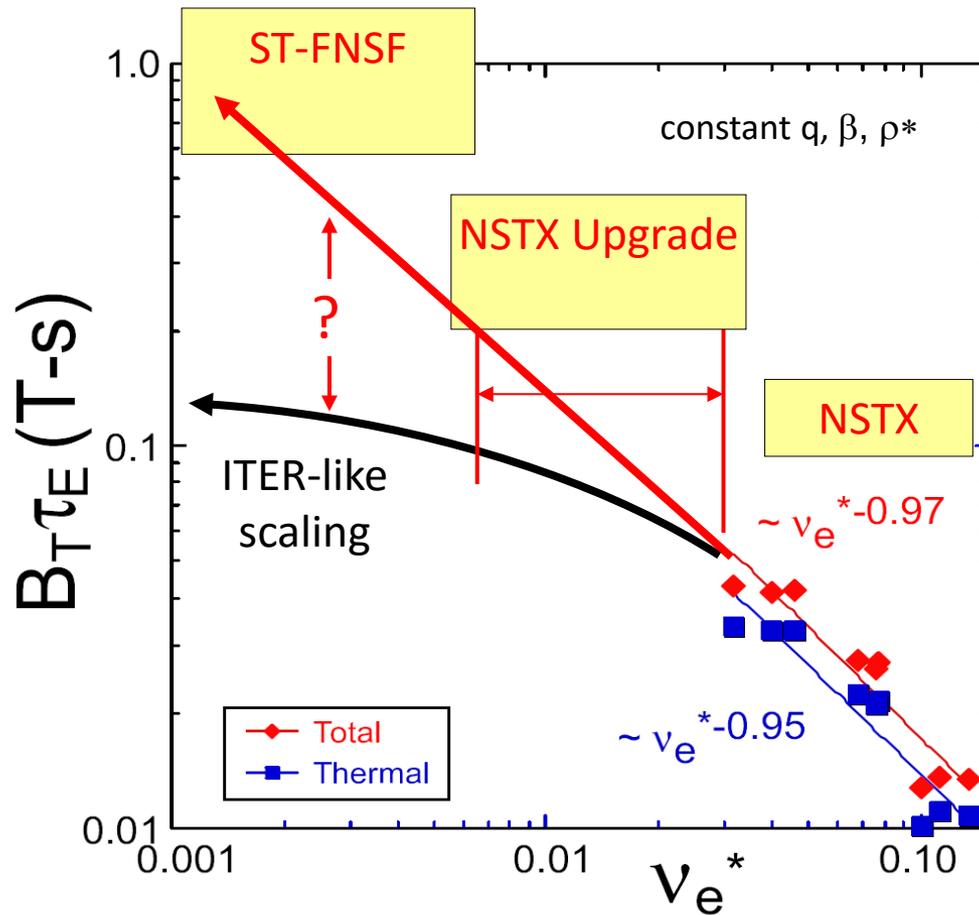

- TSC code (2D) successfully simulated helicity injection $I_p \sim 200\text{kA}$ in NSTX

Additional electron heating likely required
Design of heating system is underway...

NSTX / MAST confinement increased at higher T_e (!)

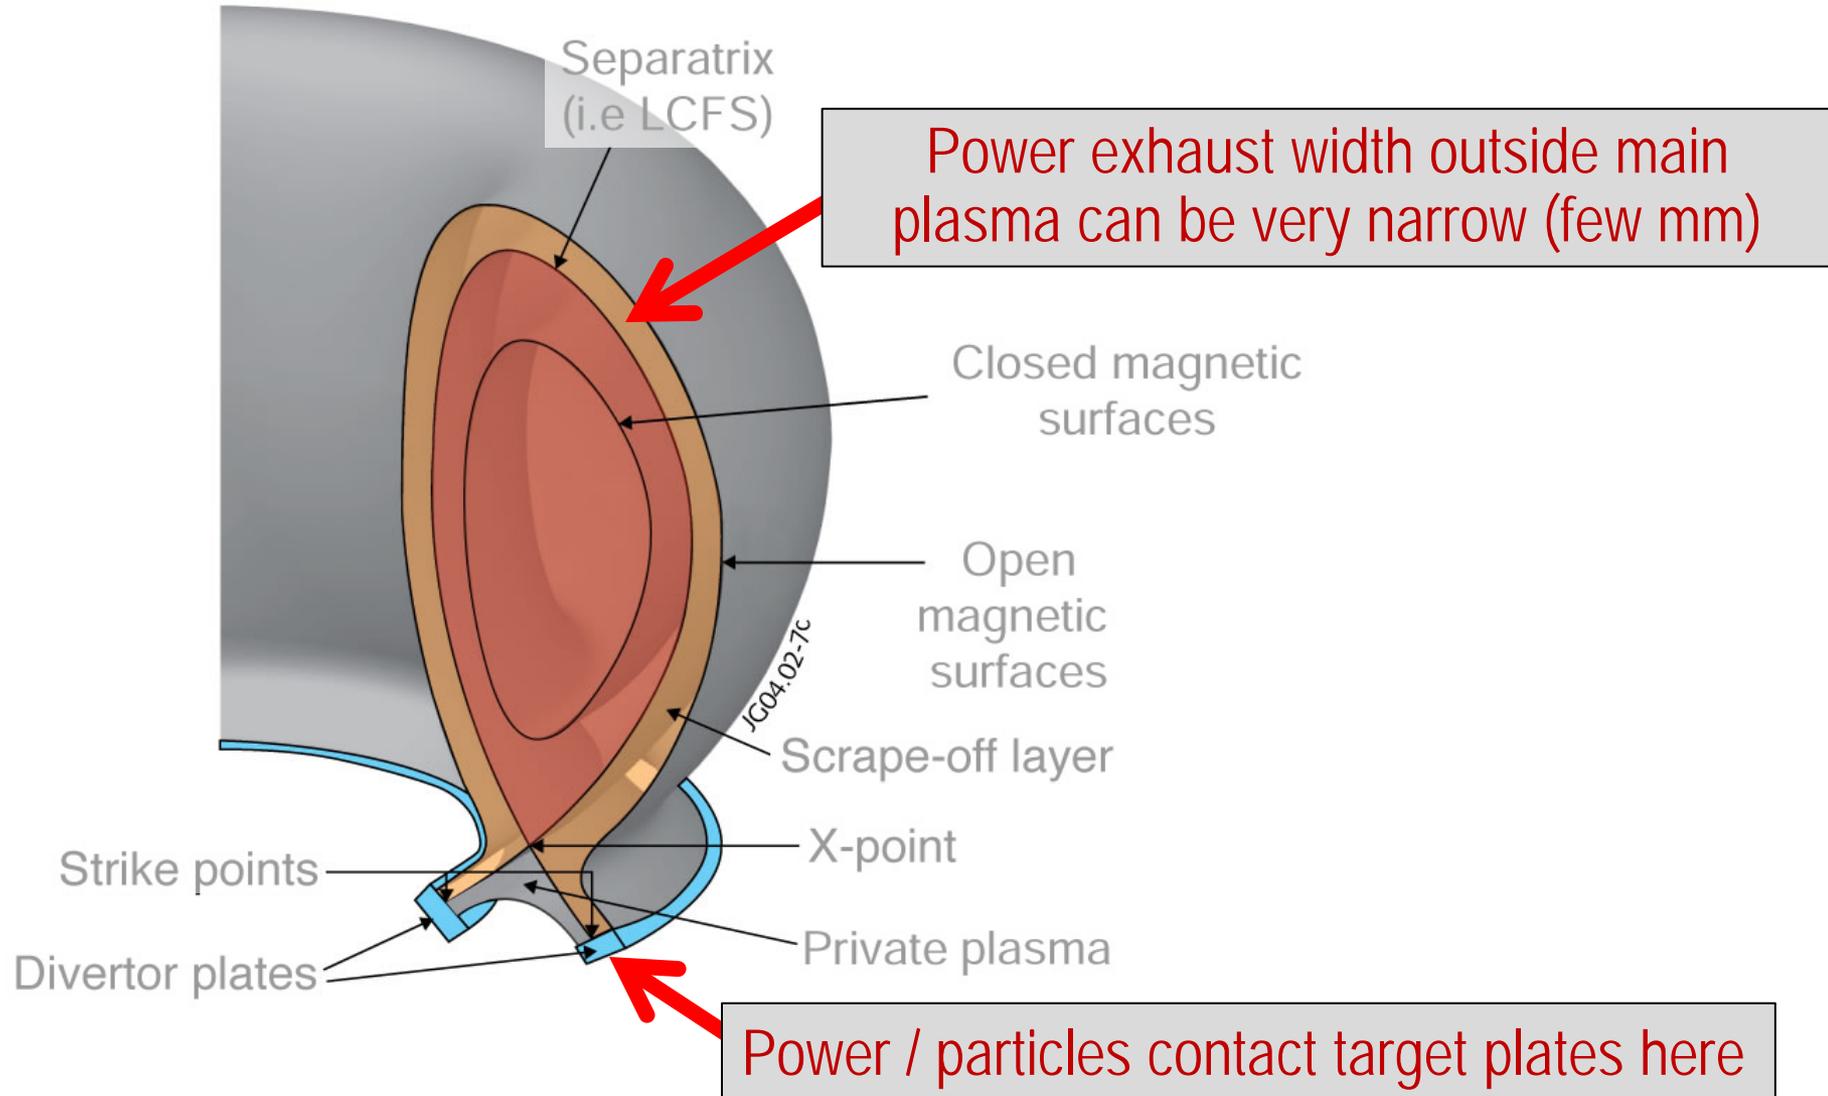

Will confinement trend continue, or look like conventional A?

Normalized electron collisionality $\nu_e^* \propto n_e / T_e^2$

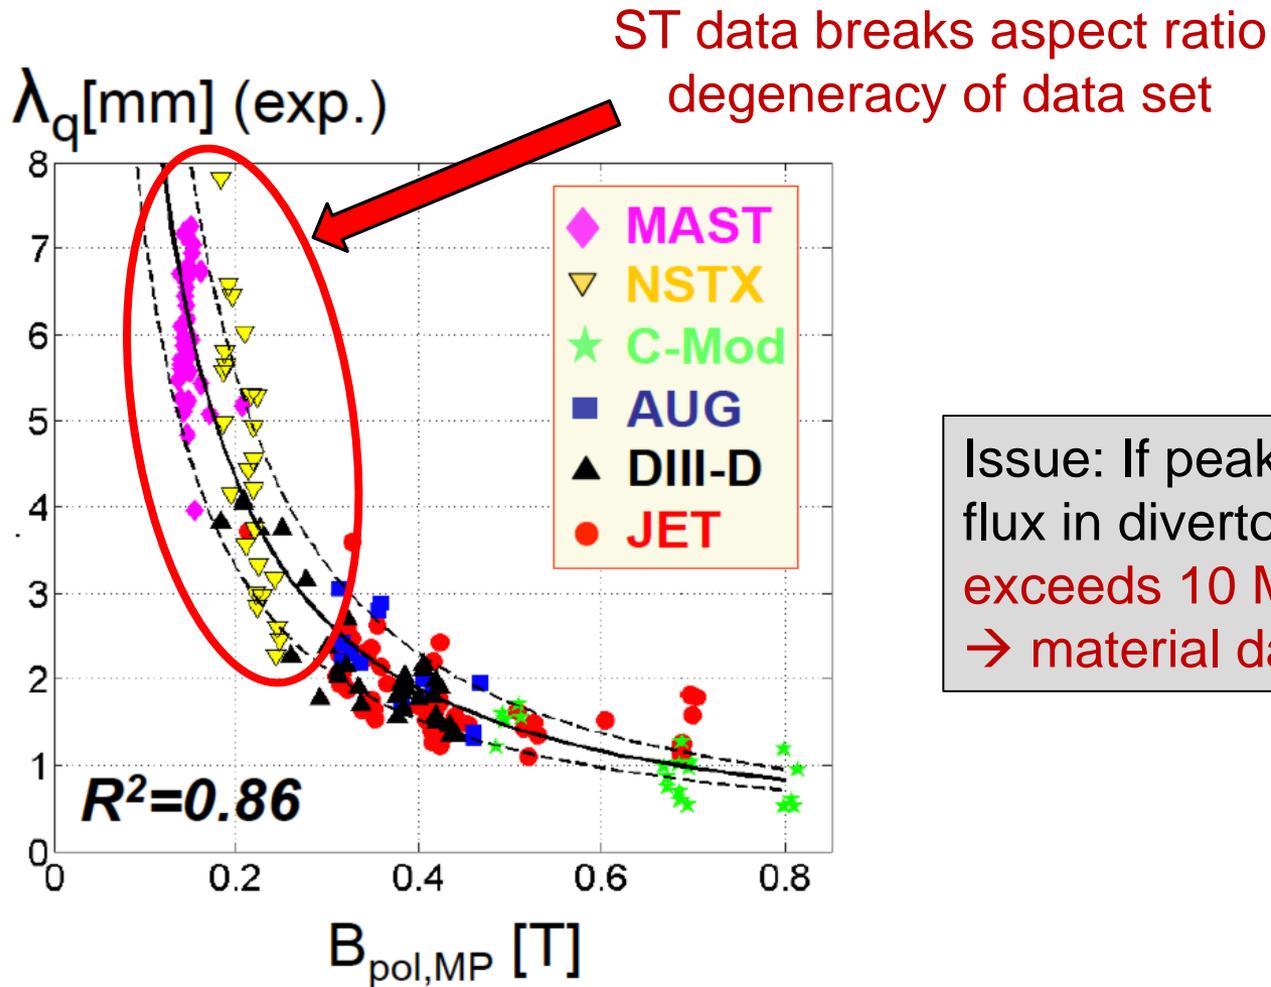

Favorable confinement results could lead to more compact ST reactors

All modern tokamaks / STs use a “divertor” to control where power and particles are exhausted

Tokamak + ST data: power exhaust width varies as $1 / B_{\text{poloidal}}$

Will previous ST trend continue at $2 \times I_P$, B_P , B_T , power?

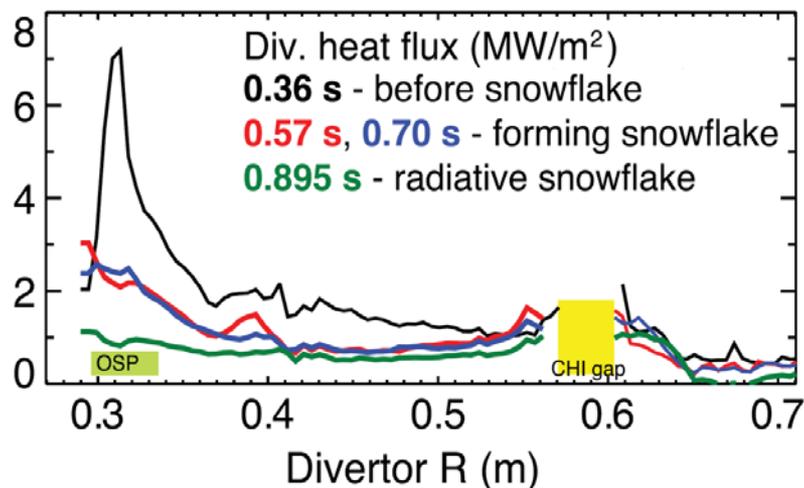

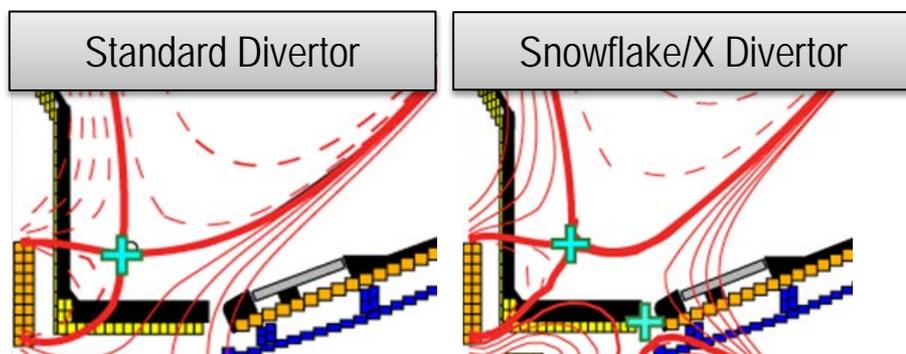

Issue: If peak heat flux in divertor region exceeds 10 MW/m^2 → material damage

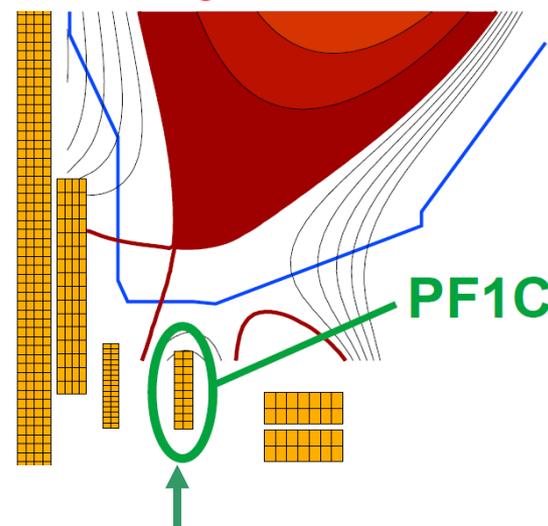

Wider heat-flux width may offset smaller R → maybe better than tokamak

NSTX-U will test ability of radiation and advanced divertors to mitigate very high heat-fluxes

- NSTX: reduced heat flux 2-4 × via radiation (partial detachment)
- Additional null-point in divertor expands field, reduces heat flux

NSTX-U peak heat fluxes will be up to 4-8× higher than in NSTX

NSTX-U has additional coils for up-down symmetric snowflake/X, improved control

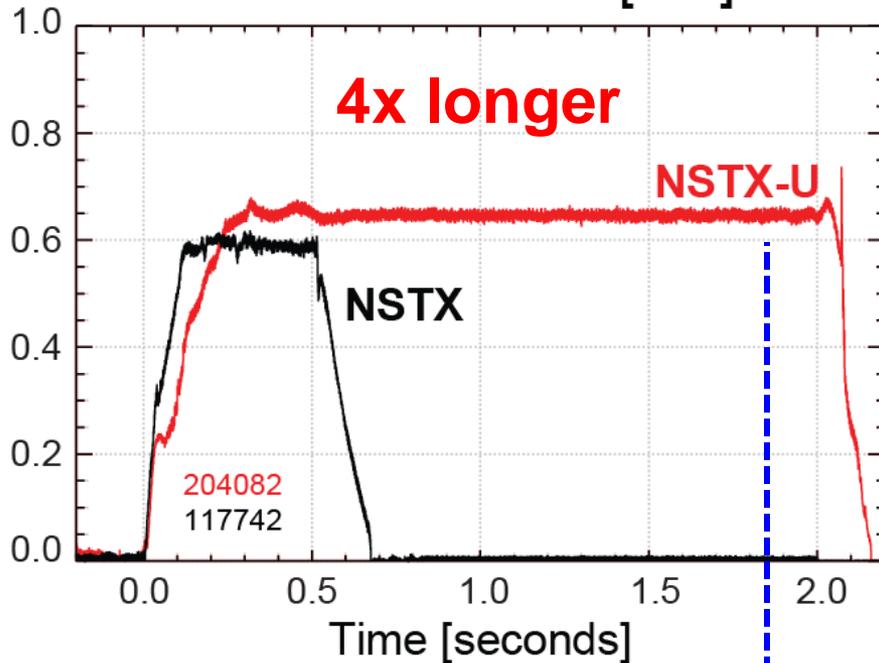

NSTX-U had scientifically productive 1st year

- Achieved H-mode on 8th day of 10 weeks of operation
- Surpassed magnetic field and pulse-duration of NSTX
- Matched best NSTX H-mode performance at ~1MA
- Identified and corrected dominant error fields
- Commissioned all magnetic and kinetic profile diagnostics
- New 2nd NBI suppresses Global Alfvén Eigenmodes (GAE)
- Implemented techniques for controlled plasma shut down, disruption detection, commissioned new tools for mitigation
- 2016 run ended prematurely due to fault in divertor PF coil
 - Coil forensics, design (re)-reviews, preparing for new coil fabrication

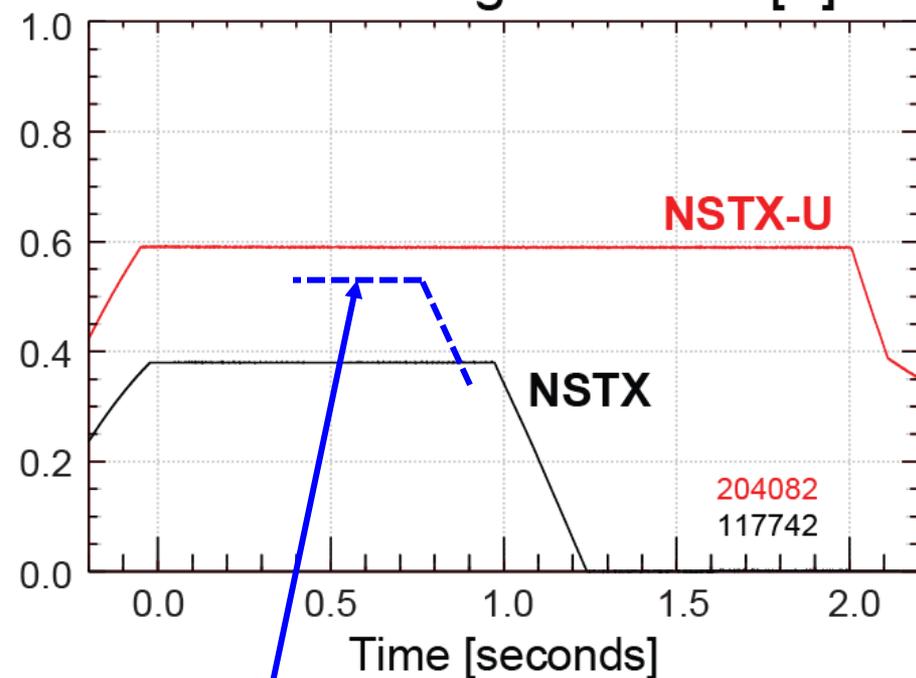

NSTX-U has surpassed maximum pulse duration and magnetic field of NSTX

Compare similar **NSTX** / **NSTX-U** Boronized L-modes, $P_{\text{NBI}}=1\text{MW}$

Plasma current [MA]

Toroidal magnetic field [T]

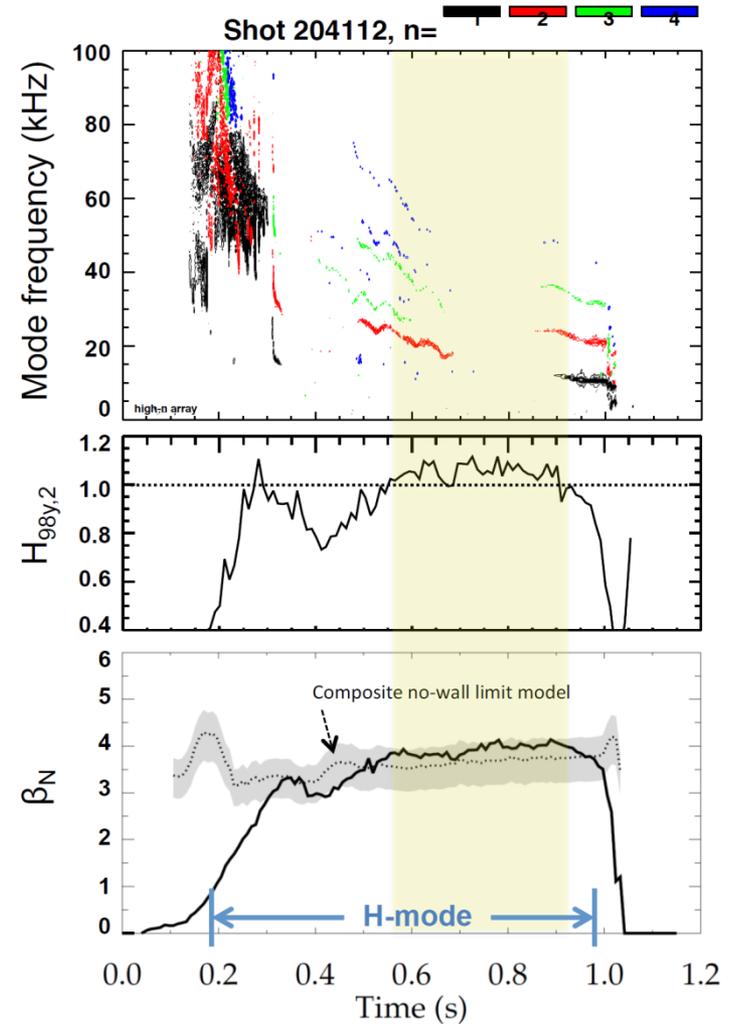

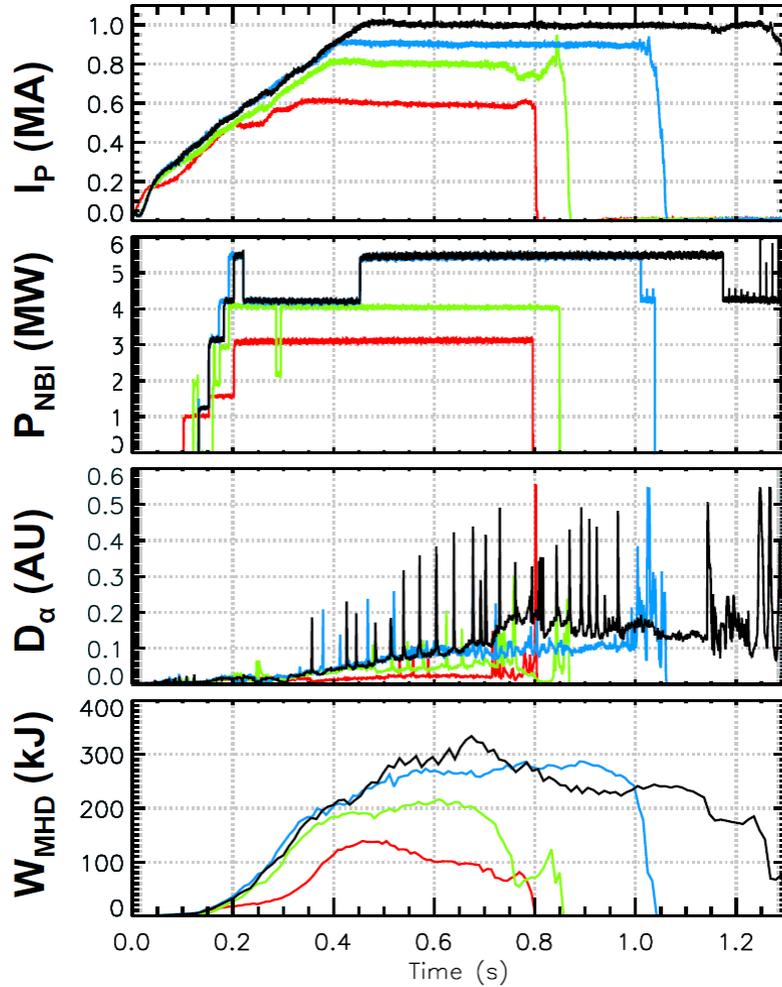

NSTX-U L-mode duration exceeds longest NSTX H-mode 

NSTX-U B_T > highest NSTX B_T

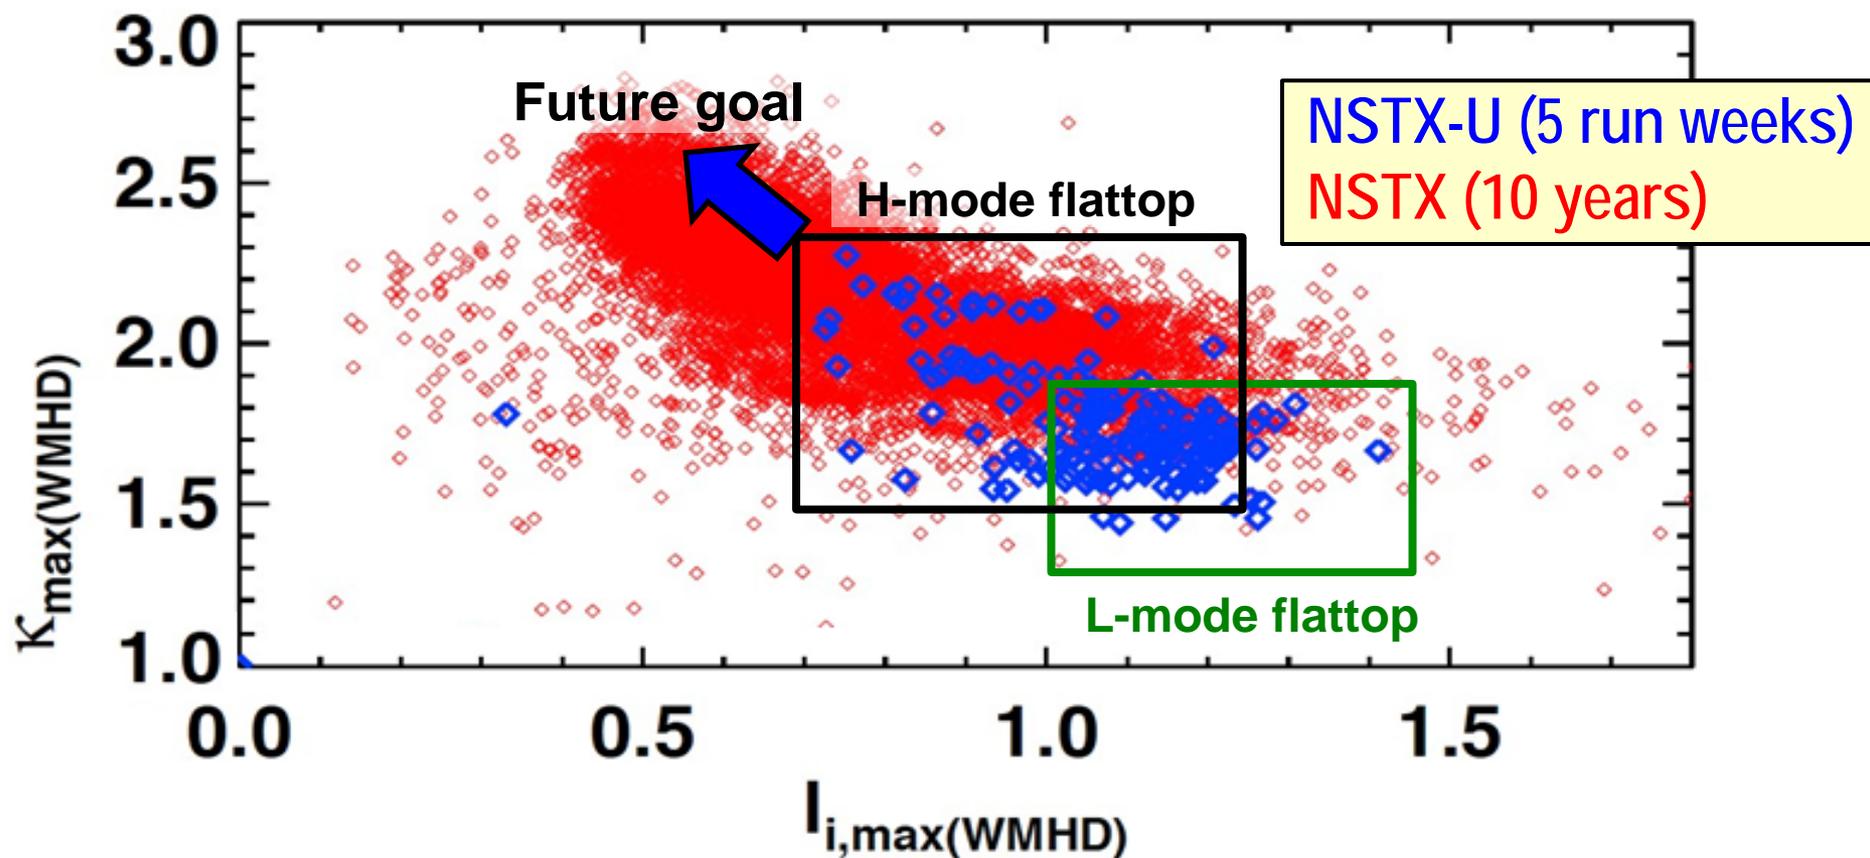

Recovered ~1MA H-modes with weak/no core MHD (comparable to best NSTX plasmas at similar plasma current)

202946 – no EFC 204112 – EFC v2
203679 – EFC v1 204118 – EFC v2

$H_{98} \geq 1$, $\beta_N \sim 3.5-4 \geq n=1$ no-wall limit

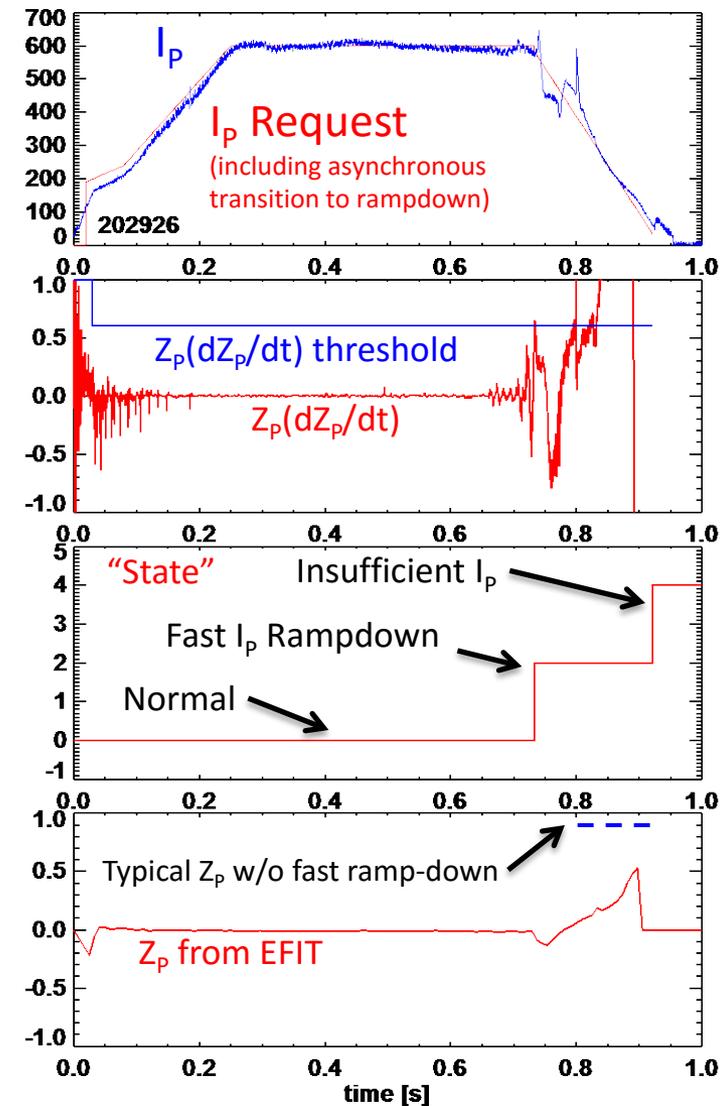

Accessed low I_i and high κ using progressively earlier H-mode and heating + optimized EFC

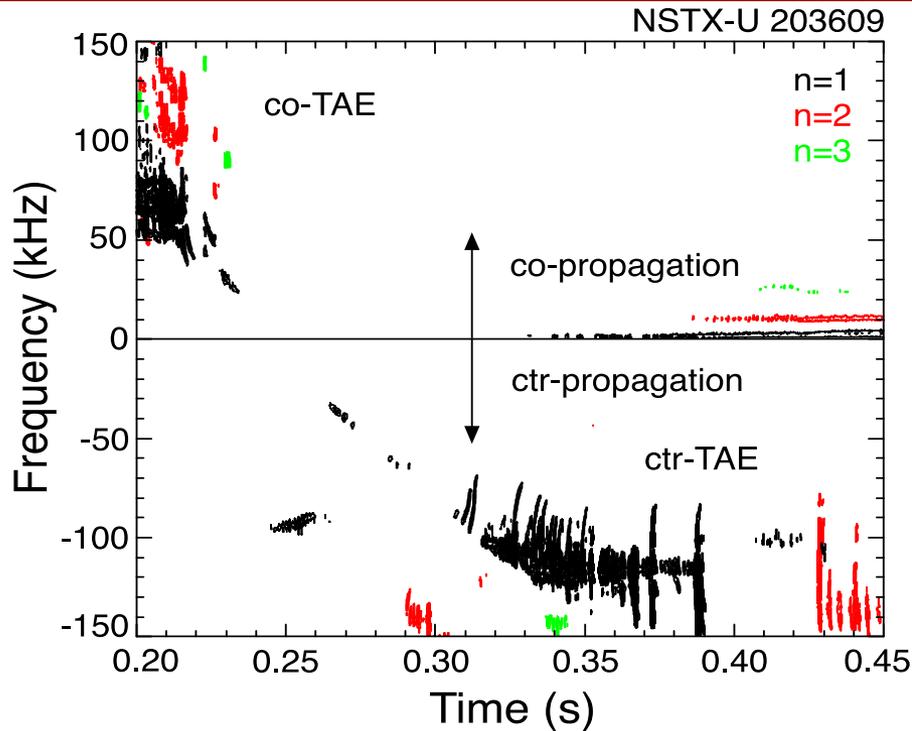

- NSTX-U: Additional sensors improve estimation of Z , dZ/dt
- Goals for next run:
 - Access $I_i = 0.5-0.7$, $\kappa=2.4-2.7$, $B_T = 0.75-1T$, $I_p = 1.5-2MA$

Implemented automated ramp-down for NSTX-U

- Plasma control system detects loss of control
 - Central solenoid coil near maximum allowed current
 - Vertical oscillations exceed threshold
 - **$ABS(I_p - I_{p \text{ request}})$** above threshold
- “State-machine” based:
 - Feedback control switches to new “states” that attempt to stably ramp-down the plasma

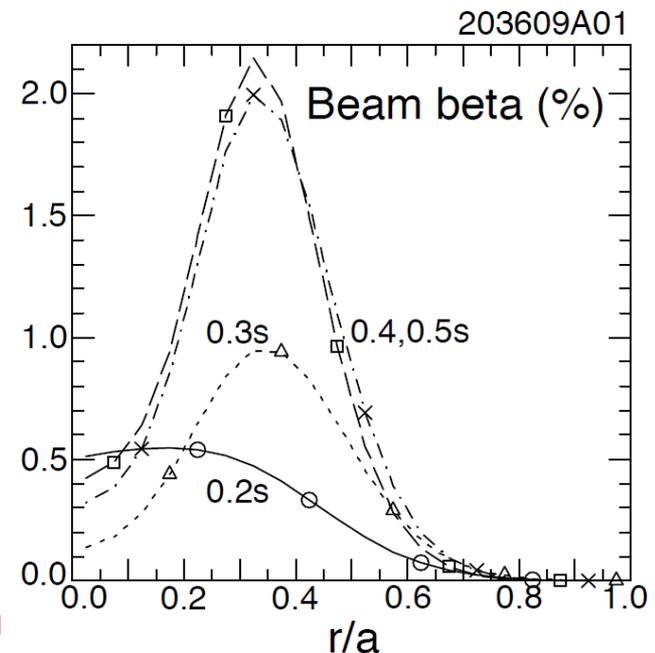

NSTX-U: Most tangential NBI generates counter-propagating Toroidal Alfvén Eigenmodes (TAEs)

- Counter-propagating TAE predicted for **hollow** fast-ion profiles

- TRANSP: As current builds up beam fast-ion beta profile predicted to become hollow

- **1st evidence of off-axis NBI deposition**

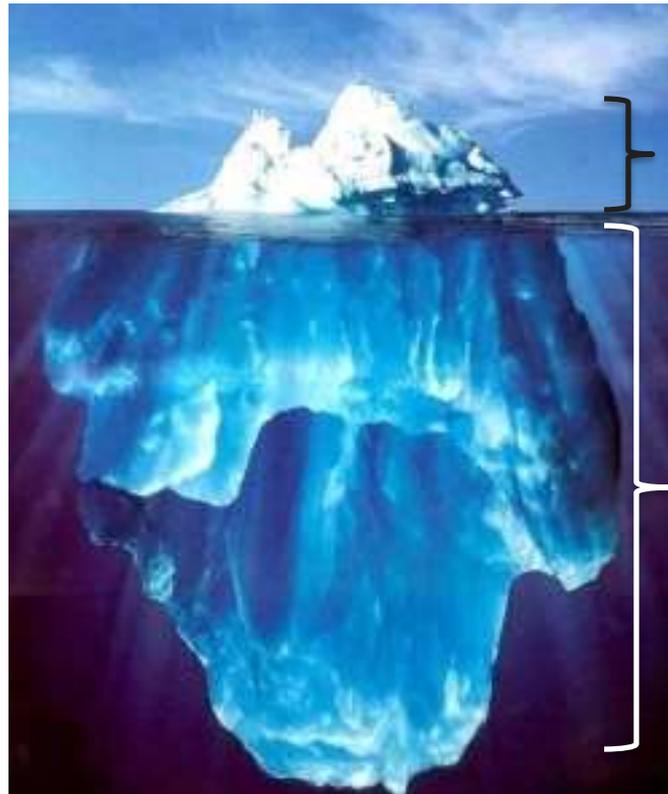

Summary: NSTX-U strongly supporting advanced predictive capability, ITER, PMI, next-step STs

- Productive first year of operations on NSTX-U
- Advancing predictive capability for core, edge, PMI
- Developed attractive ST-FNSF / Pilot concepts
- Aim to resume NSTX-U operation following repairs

➤ **See research opportunities on next slides**

Research opportunities

- PPPL has a wide range of research activities, many opportunities for novel, impactful projects
- New projects coming
 - NSTX-U
 - FLARE
 - W7X collaboration
 - ITER
 - Theory core codes
 - Liquid walls
 - Plasma-nano
 - ...

What I just showed

Active research topics at PPPL

SULI Internship

- **Summer Undergraduate Laboratory Internship (SULI) & Community College Internship (CCI) programs**
 - Paid summer internship program
 - 1 week course intro to plasma/fusion
 - 9 week project based internship
 - Also available for fall/spring semester long internship
 - Summer 2017 applications are now open!

Faculty and Lecturer opportunities: ALPhA immersion and VFP

-**ALPhA immersion** is an NSF, AAPT funded 3 day workshop for college faculty and lecturers to develop “beyond first year” labs. We run 3 workshops to develop low cost plasma physics experiments using a DC discharge apparatus (total cost <\$5k).

July 12–14, 2016, at the Princeton Plasma Physics Laboratory
Princeton, NJ

Low Cost Plasma Physics: Electrical Breakdown and the Paschen Curve

Low Cost Plasma Physics: Spectroscopy

Low Cost Plasma Physics: Plasma Probes and the Electron Temperature

Arturo Dominguez, Andrew Zwicker, and Jeremiah Williams show how to teach experimental plasma physics on a very low budget.

-The **Visiting Faculty Program (VFP)** provides the opportunity for a faculty member accompanied by one or two students to come to a national lab (e.g. PPPL) and work on a project with a host researcher for 10-weeks (time-frame coincides with the SULI/CCI programs).

Thank you!
