Motivation of XP1018

- Plasma can be more sensitive to error fields at higher- β regime, due to amplifications by plasma response
- Reliable error field threshold scaling in high- β , or H-mode plasmas is required for ITER, etc
- XP903, XP915 investigated error field threshold in high- β , and with reduced rotations by $n=3$ magnetic braking
- There are three XPs this year to extend the study
 - J. Menard : Intermediate regime across L-H
 - R. Buttery (XP1032) : H-mode regime with various different parameters
 - **J. Park (XP1018) : H-mode regime with HHFW, to reduce input torques**

Rotation is the key to error field threshold in H-mode

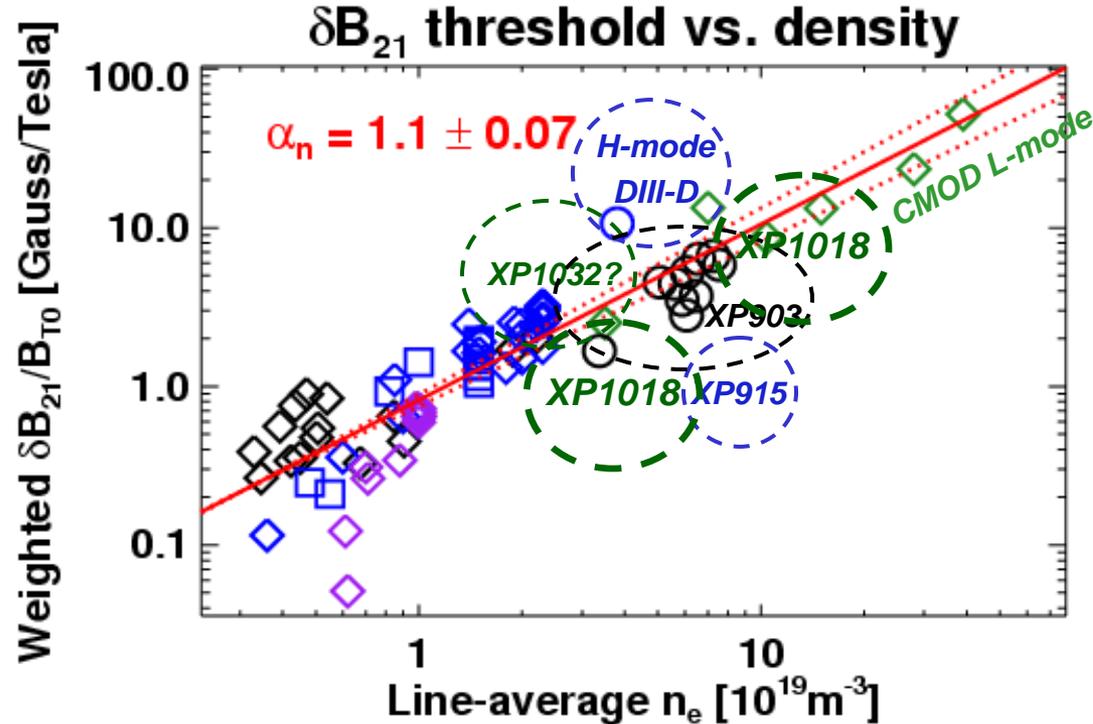

- The $n=1$ threshold becomes smaller when rotation is reduced by $n=3$ braking (XP915, R. J. Buttery)
 - Rotation (torque) is the key parameter when input torques exist

Error field threshold scaling should include rotations in H-mode

- The best parametric scaling with total resonant field:

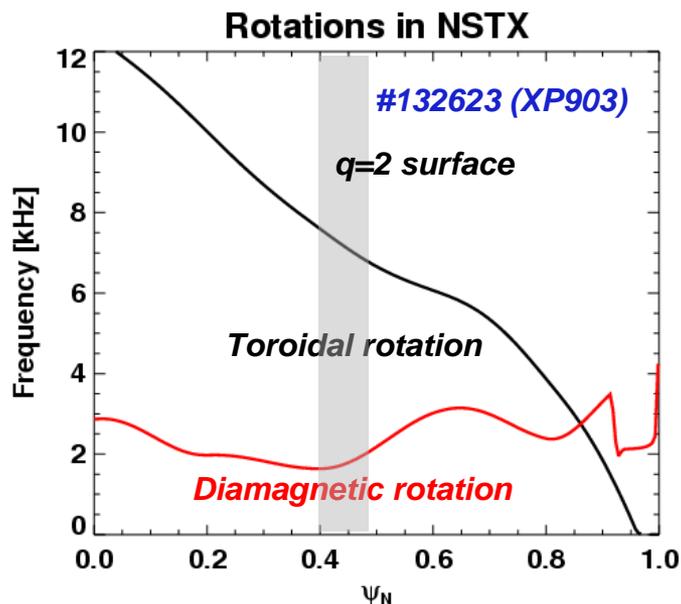

$$\frac{\delta B_{21}}{B_{T0}} \leq 0.9 \times 10^{-4} \left(n [10^{19} m^{-3}] \right)^{1.1} \left(B_{T0} [T] \right)^{-1.4} \left(R_0 [m] \right)^{0.61}$$

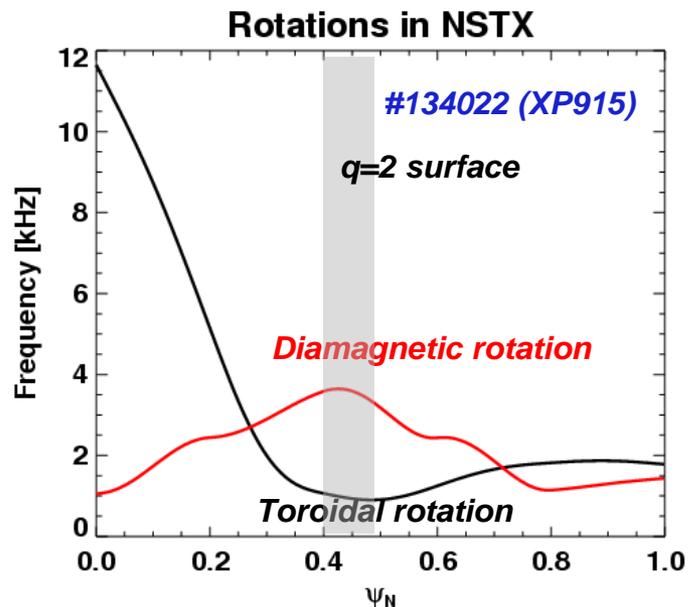

Effects by rotation on thresholds are not yet reliably quantified across parameters

- Rotation helps shielding of magnetic perturbations, and thus increases thresholds, but its effects are not yet quantified
 - What level of rotations would keep the linear density scaling from L-mode?
 - How do the thresholds scale with rotations? $(\omega_\phi/\omega_D)^\alpha$?

The case which follows the linear density scaling from L-mode

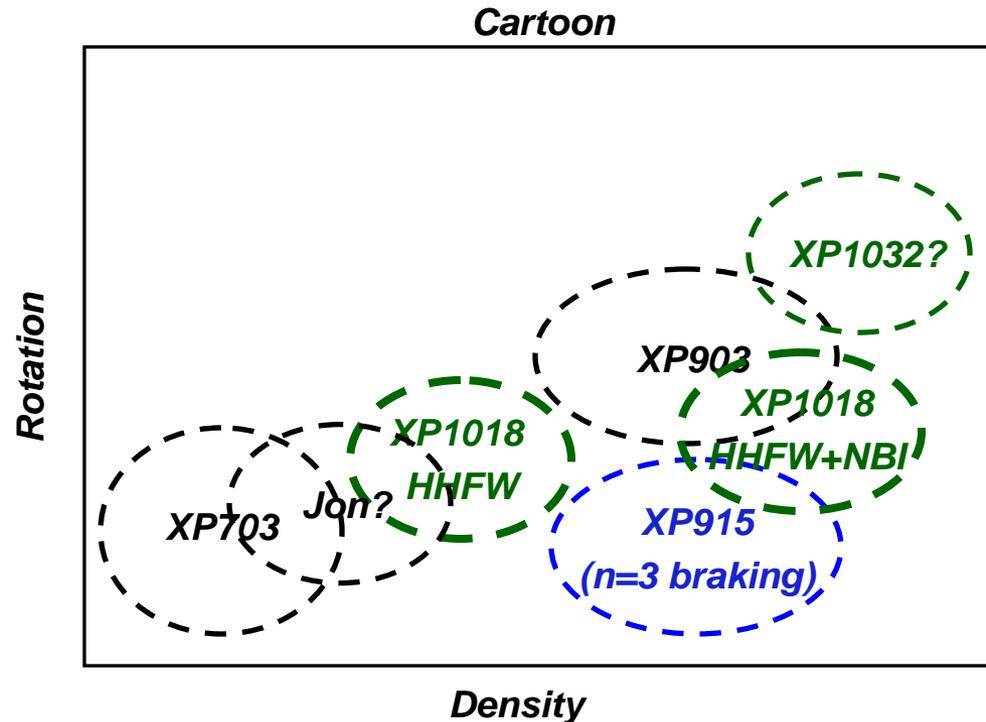

The case which is largely below the linear density scaling from L-mode

XP1018 will focus on HHFW and NBI 2MW plasmas instead of n=3 magnetic braking

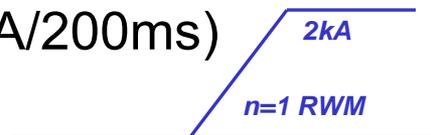

- NBI 2~3 MW (XP903) : $\omega_\phi \sim 10\text{kHz}$ (Ch.18), $n_e \sim 4\sim 6e19\text{ m}^{-3}$
- HHFW on NBI 2MW : Similar or lower ω_ϕ + higher n_e
- Only HHFW heating : lower ω_ϕ + lower n_e

XP1018 step (0.5 day)

- Reproduce XP903 with NBI 2MW (Baseline, with or without LITER)
 - Develop targets (132623, IP=900kA) (2 shots)
 - Apply n=1 currents by SPA (2 shots)
- Apply HHFW on NBI 2MW
 - Add HHFW ~1.5MW, ~3MW (3 shots)
 - Apply n=1 currents by SPA at 50ms after HHFW (3 shots)
- Apply only HHFW
 - Apply only HHFW ~1.5MW, ~3MW (3 shots)
 - Apply n=1 currents by SPA (3 shots)
 - Apply NBI A after HHFW heating for diagnostics (2 shots)

* SPA wave forms (SPA1-,SPA2+,2kA/200ms)

Other considerations

- HHFW XPs will be very helpful
 - H-mode coupling experiments, etc
 - Density and rotation vs. HHFW will be important
- LITER may be used (if it is better in terms of parametric space)
 - Stability, shot duration, density vs. LITER will be important
- Diagnostics
 - All magnetics including Mirnov arrays
 - CHERS (toroidal and poloidal)
 - TS, FReTIP
 - Edge rotation diagnostic
 - Fast cameras - divertor
